SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

105-15556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

BRIGHT'S DISEASE OF THE KIDNEYS.*

BY MORRIS LONGSTRETH, M. D.,

Of Philadelphia.

This young man, aged 25, was always in good health, till, shortly before admission, he was exposed to cold, and complained of pain in his chest; this trouble, however, passed away as a simple cold. A day or two before entering the hospital he had a slight rigor and some fever, but without further development than feeling somewhat ill.

On examination, the chest symptoms were marked, and the urine, which had a specific gravity of 1022, contained much albumen, and abundant casts. The symptoms of pneumonia passed away, but the amount of albumen very greatly increased.

I must here give an interesting and valuable point in treatment. In attacks of acute kidney trouble, dry cups relieve the pain.

On account of the tendency to congestion of the lungs and spitting of blood, this patient was given veratrum viride four times daily, but this was discontinued after twenty-four hours.

Returning to the urine, in addition to the large proportion of albumen, it contained epithelial and granular casts in abundance. I know this to be but a relighting of old trouble—why? because wherever epithelial casts are found, blood casts must have preceded them.

In order—blood, epithelial, granular, and fatty casts—you may thus trace Bright's disease through its various stages. When a patient comes to you with symptoms of kidney trouble, it is not sufficient to test the urine once for all, and, finding albumen, decide that his case is hopeless, or at least, further examination unnecessary. It is necessary to distinguish between albumen from tissue change, and Bright's disease, and a great help is searching for crystals of the urinary salts, especially *urea*.

If there be great change in the renal tubules, they cannot separate these salts, at least not enough to crystallize them. It is impossible for badly-diseased kidneys to perform this part of their work. So with casts. Albumen may be found when there is some change in the tubules; they may be too much deranged to retain albumen, but not enough to shed their epithelium.

Hence, as Bright's disease is of a progressive character, the urine should be examined quite frequently in order to keep the physician informed of the patient's condition, as this may obviously, from time to time, modify the treatment.

Our patient here was then given digitalis as a diuretic, and continued thus several days, then Basham's mixture, and later minim doses of nitro-glycerine every three hours. He is improving as rapidly as could reasonably be expected; the casts and amount of albumen are gradually disappearing. Acetate of potash was given throughout to increase the amount of urine, and with good effects.

*Abstract of clinical lecture delivered at the Pennsylvania Hospital.

COMMUNICATIONS.

ENDERMIC MEDICATION.*

BY E. G. WATERS, M. D.,

Of Baltimore.

An observant physician gave me a useful hint in regard to the treatment of erysipelas. He noticed on the person of a patient who had died of this disease that wherever the surface was dented, particularly about the head, possibly from handling the body after death, the little cup thus formed was filled, or partly filled, with serum. He concluded instantly that this resulted from overloaded vessels permitting, finally, their contents to escape through the law of osmosis, now that the vitality of the tissues no longer resisted effectively this law. He asked himself why could not this relief be given earlier, and in this way arrest morbid processes, abscess, gangrene, death, and contribute to speedy restoration of function and recovery. The nature of the morbid process seemed to be obvious. First, there was a rapid and violent congestion of the tegumentary tissues, followed by constriction and strangulation of vessels, always tending to embrace areas more and more wide, to produce constitutional symptoms more and more grave, against which the powers of life continually struggled in an unequal contest, too often followed by a lingering convalescence and a disastrous loss of substance, even when the sufferer escaped with his life. A clear apprehension of this physical condition—a condition, be it observed, purely dynamic, as viewed by theorists, yet most practical now—brought with it an almost instantaneous solution of the problem. What could be needed in such a case more urgently than the relief of the engorgement? What would contribute to this so promptly as the escape of the serum? What would accomplish this so speedily as a blister? Pathology and therapeutics joined hands, hypothesis escaped far beyond the nimbus of speculation, and needed only a subject to demonstrate the value of a conception thoroughly original, highly philosophical, and vigorously logical in its sequences. One and many cases occurred in his practice to justify his most sanguine hopes, and to verify his confident predictions. On a far larger scale and in a far more critical case than falls to the lot of the average practitioner, it afterwards became my province to employ this special method in this particular disease. I remember well hearing the late eminent Professor of Surgery in the University of Maryland say that he had been compelled for weeks together to desist from all operations, even the most trifling, in the Baltimore Infirmary, because of the certainty of their being followed by erysipelas, and of its dangerous and unmanageable tendency. In an hospital of 750 beds, where for two years the exclusive care of this disease fell to my charge, no operations were postponed or suspended, nor was the bill of mortality materially increased on this account. I say materially, for in several instances patients were admitted moribund, and may be considered to have had no treatment at all. In one case of persistent and almost malignant obstinacy, in which the central portion of the tibia had been removed to the extent of four or five inches, the disease exhibited itself nine distinct times with extraordinary virulence. The disturbing cause here seemed to be a ragged half of a bullet that had escaped most careful examination, but which was finally discovered and removed, after which there was no similar disturbance. When a student of medicine, I saw vast abscesses opened in thigh or leg, and masses of necrosed cellular tissue looking like bunches of wet tow, raised from their depths by dressing-forceps. In no case have I seen phlegmonous erysipelas ensue after the application of the blister, and in a single instance only a few drops of laudable pus made themselves visible in a minute cavity just beneath the tunic and skin. A lady 75 years old was attacked with erysipelas of the face and head on a Sunday. The following Friday evening her physician, a gentleman of culture and large experience. was kind enough to ask me to see her with him. He said he had used the usual remedies, but the case had baffled his efforts, was continually growing worse, and his impression was that she would certainly die. As she was the wife of a prominent citizen, a member of our profession, his interest was naturally quickened. I found the lady with a face and head very much swollen, though not to the extent I had observed them to be in other cases. The aural meati were closed so completely that no sound seemed to invoke a response, the eyes were deeply buried behind their tumid lids, consciousness seemed to have fled, a deep coma had settled like a cloud upon her faculties, her breathing was noisy with stertor. Certainly there was not much here to hang a hope upon, Pieces of adhesive plaster were speedily spread with cantharides cerate, and made to adapt themselves to such surfaces of the face and scalp

*Read before the Clinical of Maryland.

as were accessible, and instructions were given to let them stay until they drew thoroughly. The vesicles were then to be punctured, and their surfaces covered with a stimulating cataplasm of bran and yeast, or more properly, suitable dabs of this combination were to be applied warm, and all covered with oiled silk. Internal medication was limited to a grain of quinine every two or three hours. The blisters drew finely, with corresponding relief to the constitutional and local symptoms. Sunday evening, exactly forty-eight hours after they were first applied, the swollen features had nearly resumed their normal size, intelligent communication was re-established, food and such remedies as were indicated were readily swallowed, and breathing, even during sleep, had ceased to be noisy and stertorous. The following day vision was restored through the absorption of the effused fluids, and objects were once more naturally appreciated through exercise of this sense. In logic the *major* is said to comprehend the *minor*. This case is presented as a crucial one. Her age, the length of time that had elapsed since the attack began, the continual aggravation, the coma and other signs of meningeal or cerebral involvement, seemed to unite in a protest against undertaking further measures for her relief. Yet no success could well be more signal and gratifying than that which these measures achieved. In the instance of an army officer who had been struck with a fragment that had descended vertically from a shell exploding about his head and split open his nose, lip, and chin, and in that of the wife of a surgeon, the swelling of the face and head was prodigious. All semblance of human features was lost. The lady, especially was a monster in her deformity—a veritable Medusa—a "Gorgon and Chimaera dire"—her features were large, even when in health. For twelve hours erysipelas had wantoned over this fruitful field, and puffed it into huge distortions. The attack was in winter, and came on after exposure to a severe nothwest wind. Her husband had telegraphed for his brother, a distinguished physician in a neighboring city, but desired me to proceed at once to treat the case. This was done upon the plan already described. The blisters were applied about ten o'clock in the morning. At my evening visit her husband told me his brother had come on, seen the case, prescribed tincture of the chloride of iron, which had not been given, and had returned home. By this time the blister had drawn well, giving great relief to the burning and sense of distension of the tissues. The next morning the swelling had subsided greatly, and on the morning of the third day scarcely anything abnormal was to be noted, save the slight disfigurement left by the blister.

I recall four deaths that have fallen under my observation resulting from this disease, or associated with it. The first was that of a man who had been attacked with it above the elbow. When I first saw him nearly the entire limb from the shoulder to the elbow was a bag of pus. He was greatly exhausted, might indeed be considered moribund. The treatment consisted of tonics, stimulants, nutritive agents and the tincture of iron. He did not cease to fail, however, and soon sank.

The second case was that of a patient suffering with this disease in the head and face. He was profoundly comatose when first seen, and died in some twenty-four hours thereafter.

The third case was that of an officer whose left ilium had been smashed, probably by a fragment of shell. He told me thirteen medical men had had him successively in charge before me, and that some of them had examined his wound. Be that as it may, I took out a child's handful of fragments of bone and overcoat. The fragments of bone had become thoroughly detached, and came away easily, without resistance. One day the nurse called attention to some inflamed patches on the corresponding thigh. They were examined and found to be angry and erysipelatous in character, without, however, much elevation above the surrounding surface. They were somewhat oval or elliptical in shape, three or four inches long by two in width. Blisters were ordered for a couple of them only, under the presumption that the inflammation would yield in all when arrested in one or more, which often happens in attacks of this nature. To my disappointment, this did not occur. On the contrary, the blistered surface speedily assumed an unhealthy appearance, began to look sloughy, sank below the surface, and in a day or two became quite black. At the same time the nurse told me the patient could not be got to take any food, nor even to swallow wine. The inside of the mouth presented aphthous patches, and it is highly probable that a similar condition existed along the mucous tract of the œsophagus and trachea. He persisted in absolute abstinence from food and drink for eighty hours, and perished. At no time, however, did the gangrenous trouble deepen or extend,

and a separation around the edges of the wound indicated an effort of nature to throw off the slough, which she doubtless would have done but for life's failing powers.

The fourth and last case was the patient of a friend. He had been already under treatment for two weeks or more when my friend asked me to see him. The subject was a free-liver, a faded sport and sportsman, who had given himself to duck-shooting, card-playing, fox-hunting, and such like, with bibulous accompaniments. He had reached and turned his climacteric, and was now going down grade. His left leg, from the ankle to the knee, was aflame with erysipelas, and a slight blush extended over the instep and the dorsum of the foot. Just here, likewise, were two vesicles filled with reddish serum. The limb was greatly swelled, nearly twice as large as its fellow. The case looked unpromising, but I did not hesitate to recommend the use of the blister, to be extended over the entire inflamed surface. This was done and followed at proper time by the brand yeast, applied hot, and enveloped in oiled silk. The results were as satisfactory as could be wished. The inflammation was arrested, the swelling was reduced, and in forty-eight hours the two limbs were of equal size. But just here an embarrassment arose similar to that in the last case. The patient obstinately refused food in any form, would not take wine or alcoholic stimulants, scouted drugs of all sorts, and with an earnestness almost suicidal in its intensity, resolutely set himself to die—which he did. Nothing discouraging occurred upon the blistered surface, but a short time before his death the bases of the two vesicles mentioned underwent a gangrenous change. Discarding two of these cases in which no opportunity for treatment was given, I cannot be far from wrong in reckoning the death at not more than one-fourth of one per cent. Yet, as I shall presently mention, all these hundreds of cases were not managed in the same way.

A curious and very instructive instance of the value of vesication in this disease came under my observation a few days ago, by accident, in several senses. A young gentleman slipped on the icy pavement, and in his effort to save himself received the force of the fall on the palm of his right hand, wrenching his wrist severely. That night the pain was so distressing that he applied to an apothecary for a lotion, who with customary and assiduous alacrity gave him tinct. of iodine. This was applied, and in a short time vesicated the entire surface of the wrist and much of the back of the hand. The next morning he came to see me, complaining bitterly of his suffering, and said he had not slept for two nights. The next day, Wednesday, I saw him at home. The surface touched by the iodine was peppered with vesicles, now much increased in size, the hand, wrist, and half of the forearm inflamed, swollen, and burning. In short, he was suffering from erysipelas. The arm was kept wet with infusion of lard and opium, as little of the infusion as possible being permitted to come in contact with the vesicated surface. During Wednesday night many of these vesicles ruptured, and on the following morning I punctured with a lancet many more that seemed full of fluid. The drain from this source for twenty-four hours was surprising, and as the flow of serum went on, an abatement of the swelling and vascular injection went on, *pari passu*, with it. Years ago I noticed that an inflammatory action, sometimes no more severe than a mild erythema, and again of a more angry type, would diffuse itself over the integuments of a stump speedily after amputation, which was not readily subdued by fomentations either warm or cold, but which yielded promptly to the infusion of lead and opium. Having used this preparation often with success, I soon began to employ it for erysipelatous inflammations, whether of idiopathic or traumatic origin. In a hospital of 1500 beds, where at times as many as 300 patients came daily under the observation of one surgeon, ample opportunities were offered to test its value. This was so satisfactorily proved, that for years it has been my chief reliance in the milder forms of erysipelas. It is only where the peril is extreme, either from the violence or locality of the disease, that I now resort to the blister. At Borodino the cannon of the French thundered in vain against the Russian center, and one charge after another of their infantry was repulsed with ruinous slaughter. It was not until the "Old Guard" was hurled against their defences that their stubborn resistance yielded and the victory was won. I look upon the blister as the "Old Guard." The action of the opium infusion, when combined with lead, is often very prompt. A young man called to see me some weeks ago complaining of an attack of rheumatism in his ankle joints. Examination revealed the fact that he was suffering an attack of erysipelas of both ankles. After using the opium infusion for forty-eight hours, no trace of the inflammation remained in either of them. But

the success attending its use is not limited to congestions purely superficial. In those involving deeper seated structures its value is no less marked. I have had no case of mammary abscess to deplore since I began to rely upon it to prevent this disaster. A friend spoke to me of a case of this nature which had defied treatment, and which he then considered hopeless. At my suggestion he employed this means with complete success, and afterwards told me its action apeared to him almost supernatural, so much had it surpassed his experience with other agents in that class of cases. A lady whom I attended in her first confinement had the misfortune to have the nipples so much retracted that their extremities were much below the level of the breasts. These organs were greatly distended, nursing was out of the question, abscess with all its attendant horrors was inevitable unless the congestion could be controlled. The opium infusion did this effectually. She has since borne eight children, has always used the infusion, and has always escaped a gathered breast. In peritonitis, whether puerperal or not, in metritis, in ovaritis, in the milder forms of dysentery, in that curious form of phlebitis known as *phlegmasia dolens*, with many other painful affections, we may regard this as a sheet anchor for local treatment.

I return for a few moments to the blister. There is a great reluctance among medical men to employ this agent *early* for the treatment of pneumonia. I cannot help but think that this is a mistake. It is quite true that we do not now meet with many cases of an active type in which the prompt use of the blister is indicated, and in which it seems to exert its peculiar powers to best advantage. Certainly, I have seen an attack of pneumonia in a young and vigorous person cut short by a blister used in the early period of the congestion, with far greater promptitude than by the use of the lancet. In acute laryngitis it has yielded the most prompt and gratifying results. A young married lady called upon me some evenings ago, on her way home from a visit to a friend. She was quite hoarse; indeed, could not speak above a whisper, and said that even to do that caused her severe pain in the region of the larynx. The attempt to swallow distressed her so much that she had desisted from it altogether for some hours. The attack had come on since early morning, she said, and had rapidly grown worse during the afternoon, although she did not seem to be aware that it portended anything serious. I prepared a small circular blister about one and a half inches in diameter, and applied it carefully just at the top of the sternum. The next day, at my morning call, I found all the urgent symptoms had been relieved, neither talking nor deglutition was longer painful, she had eaten and enjoyed a hearty breakfast, a dangerous malady had been aborted, and she was equal to the resumption of her daily duties. One lady I have relieved on nine different occasions by this method. To be successful one must be expeditious. The enemy is at the gates, and the gates of life! If there is any other remedy that will meet the indications with such unfailing certainty, I do not know it. Those who have seen much of continued fever cannot fail to remember instances where the patients did not seem for weeks to be in any urgent peril. They took their nourishment, stimulus, medicine, in a mechanical sort of way, but with a clear understanding of what they were about, gave intelligent answers to questions, slept well, were easily aroused, and gave satisfactory promise of getting promptly up and around within a reasonable time after the fever had run its course. They have seen cases a little milder than these, and they have seen others several shades more severe. They have seen these patients in the fourth or fifth week, sometimes later, rarely earlier, pass rapidly into a coma more or less profound, from which, if they are not speedily aroused, it will soon prove to be the sleep of death. Now, just at this critical moment, the blister applied to the nucha will often produce wonders. During the early stages of the disease, when there is a stage of congestion apparently active, certainly extreme, its use is apt to result in disappointment. But at the later date it rarely fails to do good. A young gentleman, of some thirty years of age, had been lying sick of a fever for nearly or quite six weeks. He, his physician, and their families, were personal friends of mine, and just at this time, with the consent of the doctor, I paid him a visit of courtesy. He was cheerful, intelligent, glad to see me, thanked me for the attention. There was not a bad symptom present. Everything betokened an approaching speedy convalescence. A few days later, on meeting with his physician, a highly accomplished man, he told me our friend was very ill, and, in his judgment, hopelessly so. He requested me in a kind and earnest manner to go to see him, and to offer any suggestion to the family that might occur to me. He said further, that he had just been called urgently into the country, and could not then accompany me. The fact

of the young man being my friend's nephew relieved the situation of some of its embarrassing circumstances. I found the patient greatly changed from the condition he presented a few days before. His tongue was brown and cracked, his mouth was partly open, his breathing was heavy and stertorous, the coma was so profound that it was with great difficulty that he could be for a moment aroused. These and other symptoms at so late a period of the attack, left but little ground for hope or encouragement. As a last resource, a blister was ordered to the back of the neck, to extend some inches down the spine. Happily he had had the best attention, good nursing, been well sustained—the blister drew well, and in twenty-four hours he was out of danger.

What has been said hitherto has had reference exclusively to adults. I have not met with a practitioner who uses quinine endermically with children. And yet this use of that remedy is replete with benefits and advantages not easily appreciated except after trial. The distaste children have for the drug in any form by the mouth often presents an insuperable difficulty to its employment in that way. Besides, when swallowed, the lingering bitterness of its taste will often cause its rejection, and that too when it is important that it or one of its congeners shall be given. To dissolve it in whisky, and have it rubbed into and through the child's skin, does away with the above-named objection, and substitutes a method exhilarating and fairly intoxicating in its effects. Young infants soon learn to look for the rubbing with some of the eagerness that an older voluptuary welcomes the sensuous enjoyment of a Turkish bath. These poor little wan shadows of their former selves, shriveled and shrunken by heat and cholera until their vital forces almost refuse to perform their various functions, will often start into new life under its favoring action. I order about a scruple to be mixed with an ounce of whisky, and of this from half a drachm to a drachm to be rubbed in along the spine night and morning. Too much force must not be used, else the back will become sore. In intermitting fever, no surer way than this can be employed to stop the chill, and put the little patient on the high road to recovery. Indeed, with adults I have used this method with equal success, In the case of a gentleman past 75 years, the third chill was stopped, and he never had another. He had a fancy that quinine disagreed with his stomach, and preferred the above way of using it, and it proved completely successful. A young lady, much given to drawing, had several nervous attacks, far from being distinctly hysterical, which proved troublesome, and threatened to be serious. During a visit to Atlantic City, some fever came on every day, and she hurried home to escape a spell of sickness. Treatment did not afford the relief one had a right to expect from it. Languor, loss of appetite, nausea, and broken sleep, refused to yield to usual remedies. Assuming that there was some spinal irritation at the bottom of the trouble, I directed her spine to be rubbed twice daily with quinine and whisky, with possibly a little strychnia. The result was prompt and surprising. Her appetite returned, she was soon able to exercise without fatigue, her sensations and tastes became natural, and in two weeks she was restored to more than her average health. The addition of strychnia and arsenic to this formula *pro re nata*, will often be found highly serviceable. In the case of our little patients feebly and languidly convalescing from any form of disease, and of those who may be regarded as the victims of our crowded cities and of our artificial life—the Tiny Tims and Paul Dombeys of our current civilization—great results may often be secured from this push from behind. In those without constitutional taint, where mere feebleness and arrest of metamorphosis exists, often consequent, it may be, upon a lowering of nervous force, we may expect with confidence rapid impairment and speedy restoration to vigorous health. And even in those where the lurking worm in the bud precludes the prospect of perfect recovery, much *malaise, ennui*, and actual suffering may be relieved or prevented.

Horace tells us it is difficult to discuss common things properly. In these remarks I have striven to avoid trenching upon the province of specialists. Indeed, the general practitioner must be like Pope's squinting poetess,

> "To no one muse does she her glance confine,
> But has an eye at once to all the nine."

It has been my object to do what Bacon advises, to present the subject and thus seem to lead the dance. Its possibilities are not limited to the agents nor the derangements noted in this paper. To use Newton's fine figure, we are all like children gathering a few pebbles from the shores of the ocean of knowledge. The King of Brobdingnag told Gulliver he valued the man who had caused two blades of grass or two ears of corn to

grow where only one had grown before more highly than the whole race of politicians. To relieve pain, to shorten sickness, to prolong life, to introduce improved methods into the science of therapeutics, may not satisfy entirely the demands of an honorable ambition, but may justify us in feeling that we deserve at least the encomium of this wise and illustrious monarch.

ACUTE INEBRIETY.

BY T. D. CROTHERS, M. D.,

Superintendent Walnut Lodge, Hartford, Conn.

A man who has been a total abstainer for a lifetime or many years, or who only uses wine at the table, will suddenly drink to great excess, be intoxicated, and exhibit an acute mania for spirits, that indicates profound cerebral disorder. This mania is characterized by impulsiveness, precipitancy, and often by a degree of cunning reason to procure spirits or conceal them for use that is bewildering to the ordinary observer. All the talents and native force of the man seem to be concentrated in one direction: to procure and use spirits. Opposition and difficulty seem to bring out latent qualities of energy and reason not noticed before. He drinks to stupor constantly, only satisfied with profound narcotism. If unrestrained, this state merges into an acute fever and low muttering delirium, which calls for active medical interference. In some cases the period of convalescence is short, in others it is long and followed by complicating diseases, of which gastritis, acute rheumatism, pleurisy, or pneumonia, are very common. In some cases the drink storm seems to have ended, in other instances it begins again with renewed energy and impetuosity.

In a few cases this drink mania continues up to death, only checked by forcible restraint and inability to procure spirits. In other cases it seems to have exhausted the germ soil, and dies out forever, or after a long interval springs into activity again.

When the inebriety comes on suddenly and is precipitate, it may be the explosion of a nerve state, which will die out soon, or be the beginning of an acute mania. The following case is an example of the latter:

A——, a merchant, who had overworked for years, and drank wine at meals in great moderation, suddenly became intoxicated and continued so for weeks. He came under my care, and after six months, went away greatly restored. He began to drink again and was returned, went out, and relapsed, then was taken to an insane asylum demented. The drink period lasted nearly two years before the final termination in insanity.

B——, a lawyer, began to use spirits to great excess, and was locked up in jail for ten days. From this time for the following five years he drank to intoxication with every opportunity, and sought, with great skill and cunning, means to procure spirits. He was under my care, but was without power of self-control, and always drank on every occasion. On one occasion he remained concealed at the house of a friend for two months, intoxicated nearly all the time. Finally, he became melancholic and suicidal, and was placed in an asylum, where he is now a chronic dement. The premonitary symptoms, or drink period, lasted over five years.

The cases of inebriates who, after a short or long stage of drinking, stop short, and remain sober an indefinite time, are more numerous. These are not periodical inebriates, and have no regularity in the return of the drink paroxysm. In the midst of a quiet temperate life they suddenly, without the slightest apparent premonition, drink to intoxication, and keep it up as long as opportunity and ability to take spirits continue. Or, in some cases, they stop as unexpectedly as they began. Take the following cases:

A——, a neurotic, with an alcoholic ancestry, who had used wine at the table for years, went to his business one morning, finished his correspondence and other duties, then went to a hotel and drank to stupor. He was found four days later at the hotel, profoundly narcotized, and taken home. Here he continued to drink for weeks to great excess; no efforts could stop him; finally an old friend called and expressed sorrow that he should continue in such a course of conduct. At once he expressed faith in being able to stop, and from that moment reformed and did not drink again for four years. Then he relapsed, and after much effort he was brought to my care; for many weeks was exceedingly difficult to manage, then he suddenly announced that he was going to change, and from that moment he abstained for two years. Then he drank for three months so excessively as to alarm his friends, and finally wandered into a church prayer-meeting, expressed a change of heart, and reformed again. Both the beginning and ending of these paroxysms were uncertain events that could not be foreseen (or at least were not by any of his friends).

B—— was a mechanic who was temperate

and well up to a certain point where he was successful with the sale of a patent, when all unexpectedly he went away and drank to great excess, and was intoxicated for many weeks, until he was prostrated with a severe fever. He recovered, and two years later relapsed, and stopped in the midst of a wild drink paroxysm. Another long free interval was followed by a similar relapse and sudden ending.

In these cases the only remedy was forcible restraint and medicines to produce powerful and sudden impressions on the organism. In one case a physician related to me an instance where he gave such a case a severe whipping for some indignity to his wife. The excitement and injury the inebriate received sobered him, and he continued a sober man from that time. The shock to his nervous system produced a permanent impression for good. Many instances are recorded of a similar nature, which point to some state of nerve and brain shock, or to the exhaustion of the drink impulse.

The reason and judgment often exhibited in these cases when using spirits indicates unusual sanity and clearness, and the layman can only explain it by the terms vice and malicious wickedness. Literally such cases are reasoning maniacs of the most dangerous character. The following is an example:

A——, the son of a rich man, who had no business, and whose ancestry were both alcoholic and neurotic, would, after a long period of total abstinence, drink to intoxication. After a few days of alcoholic stupor, he would apparently recover, although still drinking to stupor at night, manifest the most extraordinary cunning and judgment to procure money and distress others who had in any way incurred his anger. He would forge and raise bank notes, plan and carry out schemes to bring distress, such as having persons arrested late Saturday evening on false charges, start stories and rumors where they were calculated to do great harm, plan schemes of swindling of the most adroit character, etc. In all this he would be concealed, and never be legally responsible. He would have a number of retainers who would always seem to be the guilty ones. This paroxysm of malice and intrigue would end in a few weeks, and he would show great sorrow and interest to repair the injury. He never acknowledged any participation in these events, but he sought to save the victims or the actors from the legal consequences. In this case the shrewd calculation and judgment of human nature seemed so unusual in a man who drank to stupor almost every night, and his great frankness of manner and conduct to his friends gave no indication of his insane cunning. Had a crime been committed, all the general evidence would have pointed to a mental state fully comprehending right and wrong, and the nature and consequence of his acts, and yet he was a most complete maniac.

This case was an extreme example of moral insanity and reasoning mania. A more common and familiar type would be the following:

B., a merchant who at long irregular intervals drank to stupor, would, during the half-sane moments of the drink paroxysm, plan to conceal his property and arrange to have spirits within his reach. He would profess to try to recover, but in reality be planning and carrying out the most adroit plan to lengthen out the paroxysm, and also to avoid paying debts. Often these cases come to an asylum, and the skill and resources of the managers are taxed to the uttermost to check them. A periodical inebriate can be reached and understood by the expert; also the constant drinker and the dipsomaniac, and the inquisitive accidental inebriate. But these sudden acute inebriates present unusual difficulties in both study and treatment. The almost infinite variety of symptoms and mental phases of disorder bewilder the observer, who while recording them is fully conscious that from a wider study they will be understood, and the laws which govern them known. At present he can only observe and put down the facts, leaving the conclusions to others. These cases require prompt medical care and attention, and should be recognized at once by the physician. In one instance a man of this character is brought to my care (forcibly) on the first appearance of the drink crave. In a few days he fully recovers, and is very grateful for the restraint.

In another case, a prominent man is taken to an insane asylum, and locked up in a room for a few days, with the same good result.

In some cases I have advised to use restraint at home for two days or more—until the paroxysm has passed. The first thing is to place the person under restraint of some kind, suitable to prevent him from using spirits. Often this can be done by the most varied means and surroundings; and sometimes chemical restraint is sufficient. In all cases the object of the physician is to cut short the paroxysm, or, at least, temporarily prevent it, in hopes that it may die out or

become exhausted and not return again. It is criminal negligence to permit such a case to roam about free and acting under the impulse of a diseased brain and will-force. No matter how sane he may appear in act or conduct, if he is found to use spirits suddenly and to excess, he is a subject for medical inquiry. Many of the sudden, mysterious disappearances of men of standing in large cities are of this class, and in their stupor they are either killed or sent away on some ship. They are men of temperate habits, the drink paroxysms which have occurred at long intervals, and been concealed, are not considered as noticeable, because the stupor has been of short duration. The most of his conduct has been marked by seemingly full appreciation of his surroundings. In some of these cases where the reported disappearance of a prominent man has excited attention, the victim, after recovering from the first stupor, and partially realizing that he was being hunted up, has, with a criminal cunning, taken every measure to conceal his presence, with success, often baffling the shrewdest detectives. Here the skill of a maniac is often displayed. Later, when these cases are found, no mention is made in the press out of respect to the feelings of friends.

A man of some wealth, who had been a patient of mine, disappeared in Boston from his friends, and for many weeks a large detective force failed to get any trace of him. He finally came to my place for treatment thoroughly disguised, having spent his time in eluding the detectives, and in moderate and excessive drinking. This drink storm had died out, and the pleasure of keeping away from the detectives and using spirits was waning.

The practical fact to be remembered is to study these cases as veritable insanities, and treat them on this basis. A vast field for the most practical clinical research opens up about these cases, and physicians of all others are most competent to explore it.

Medical Societies.

CHICAGO MEDICAL SOCIETY.

(*Concluded from page* 366.)

The question of introduction of fluid into the air passage may not be a tangible objection. But we would perhaps prefer to select the kind of fluid we would put into the trachea instead of milk or beef tea, or anything of that kind. The operation of tracheotomy has been resorted to for a great many years, with varying success, by different operators and in different localities. Trousseau, years ago, reported his success as about one in three, or three to four, from a very large number of cases. In the cases we have heard this evening as compared one with the other, tracheotomy hardly holds its own. The number of cases of tracheotomy no doubt are not all reported, but a fair proportion of them probably have been reported. While tracheotomy is certainly of great benefit, and has proved itself to be such in this class of diseases, it is subject to its disadvantages and annoyances; but so also has intubation its annoyances, both to the patient, the friends, and the doctor.

Dr. C. T. Parkes: I have nothing but words of commendation as far as Dr. Waxham is concerned, for his persistence in presenting this method of O'Dwyer to the profession of this city. I have nothing to say about intubation; I have no experience, never having seen a tube used. I have had a little experience in tracheotomy, and so far as my personal experience goes, I shall stick to that until I have reason to change it. My experience extends over thirty-one cases of tracheotomy. I had the honor to report to this society on previous occasions the first fifteen cases; eight recovered and seven died. I have collected the names and residences of sixteen more, and of these ten have recovered and six died. That is a pretty fair showing. I cannot explain, do not pretend to explain, this percentage of recoveries. You will find in the literature of tracheotomy throughout the world that some operators have a good fortune in that respect. I do not think it an unusual or peculiar fact that the doctor relates about relief given to the patient when you open the trachea after stenosis; in cases in which the patients are unconscious, black in the face, and are revived by the introduction of the laryngeal tube, such a result is to be expected. I see by the report very few if any of these cases recover after intubation; I know I have seen just such cases recover after tracheotomy. I have never had any trouble from the swallowing of fluids or food of any kind; I have seen the fluids come out of the opening of the tube, and have had the physician in charge reporting that we had unfortunately made an opening into the œsophagus; those cases have never given trouble, and in a few days subsided. There is one peculiarity about these cases of intubation, that Dr. Bogue has explained, the pressure of the tube causing an early disappearance of the membrane. There have been no

cases that I have seen in tracheotomy, where the tube could be removed under six days; in two cases it was three or four months before the tube was removed; I have never seen the trachea opened so far, without seeing false membrane come out of the trachea. If I were enabled to remove the tracheotomy tube inside of six days or a week, I should think that to be a case in which no membrane was found in the trachea, and one, in all probability, if I had waited a few days, in which the patient would have gotten well without any operation. There is something peculiar and interesting in the ages of these sixteen cases, the youngest being 3½, the oldest 37 years of age. I think the cases in which stenosis has been complete, and required an opening of the trachea, have been very few in the adult. One of these operations was upon a woman after she had been sick some four or five days with a bad case of pharyngeal diphtheria. At the time I saw her she was absolutely suffocating, and I was called for the purpose of performing tracheotomy; I did the operation under very poor surroundings, and yet the patient recovered. The tracheal opening became diphtheritic. Another case was 32 years old. The patient died on the table; this accident has happened in quite a number of cases. I never had any trouble with the children, and certainly expected less with the adults, as in the latter the operation is much more simple than in the child. This patient stopped breathing before the trachea was reached, and after it was opened it was impossible to restore respiration. As far as I am concerned, I can say nothing about intubation. I think it is very likely I shall purchase a tube. I don't know whether or not it is such an easy thing to intube the larynx; I think I have cognizance of three cases not in the doctor's list that proved fatal, in which some difficulty was met. One 3 years old died the day after; one 7, in which no relief was given, as the membrane seemed to be pushed ahead of the tubes; and one in which, no relief being given, the attempt to remove was complicated by the child swallowing it and being buried with the tube in its stomach. Another, a young lady 17 years old. This patient recovered; she was relieved immediately after the introduction of the tube, and rested very comfortably until the next day, when she complained of a pain in her stomach. In the evening of that day she passed the tube from the rectum. I allow you to judge of the necessities requiring its use, so I don't know that I can agree with these gentlemen and say the operation is simple. We know what tracheotomy amounts to, and I am sure I would not feel right about it, I should be haunted with the idea of not doing my whole duty, if I left a child 7 years old go without doing tracheotomy where I felt satisfied, after this tube was introduced, there was no relief given. I think tracheotomy will always have a place. I have been asked so many times how I come to have this record of tracheotomy, that I think it is due me to say one thing more; I do not know how to explain it. I believe no other operation for tracheotomy should be done but the high operation. The trachea should be opened at the highest ring, and if necessary, divide part of the cricoid, as I have done, or all of it. Certainly the after care has a great deal to do with the recovery, and I do not believe there are any persons so wanting in intelligence, but if you give them instructions carefully they will carry them out. So far as my experience goes, the surroundings have made no difference, even if it be a house of only one room with the whole family living in it, and several other animals besides. I think the room should be kept at a temperature above 80°; there should be no attempt to fill it with moisture, the room should be so hot as to be decidedly uncomfortable for all the friends, for the first twenty-four hours. During this time (twenty-four hours), the inner tube of the trachea should be removed every hour whether the patient seems to need it or not, because that is the time when the deep-seated trouble in the organs below starts. After that time I do not believe the tube should be removed oftener than seems absolutely necessary, and I do not believe that mucus can be prevented from drying by the introduction of foreign bodies. Every time the tube is removed it should be re-introduced damp, or wet in a mild solution of soda, and occasionally without taking out the inner tube, drop into the trachea a few drops of this same fluid, so as to keep the end of the tube as moist as possible. No foreign bodies of any kind should be introduced into the trachea after you are quite certain all the pieces of membrane have been detached and removed at the time of the operation. The introduction of such an innocent little thing as a feather or sponge I am satisfied does more harm than good. I am willing to admit that in one case which showed every sign of recovery, the tube was moist and the cough was moist, and I had every reason to believe it would get well, but owing to over-anxiety I kept poking feathers into the trachea, and had the friends do the same, until I got up an inflammation of the

trachea proper around the tube, which I am satisfied was the cause of the fatal issue. I do not think there should be any interference; the least possible interference is the best plan of cure.

Dr. H. T. Byford said: I wish to call attention to one fact; that is, in the statistics of hospitals tracheotomy shows about as favorably as intubation, although in private cases the safety, simplicity, and absence of formidableness of intubation makes it already the popular operation. As I have said before this, tracheotomy is an operation for hospital practice, where the difficulties can be overcome, and where its just claims for precedence in particular cases must always obtain consideration.

Dr. F. E. Waxham, in closing the discussion, said: I believe every tracheotomist will entertain an opinion in regard to tracheotomy according to the success which he has attained. If a physician has saved every patient upon whom he has operated, he will feel that the operation is good enough, and will be perfectly satisfied; if he has saved a large proportion of his cases, he will be loth to accept anything new; but the great majority of physicians, who have either met with unvarying failure or inferior success, will have a poor opinion of the operation. English writers seem to be losing faith in tracheotomy, for Holmes, in his "System of Surgery," says: "English medical men seem very generally to incline to the opinion that the operation, if not to be recommended, is at least justifiable, but to be successful it must be performed at a very early period of the attack." Referring to Professor Parke's remarkable record of tracheotomy, I cannot help feeling that his cases could not have been so unfavorable. I cannot believe that he had many young infants to operate upon. I would like to ask the age of his youngest patient.

Dr. Parkes: Three and a half years.

Dr. Waxham: That explains why his record has been far more successful than that of many physicians. I believe that if tracheotomy were performed upon every case without reference to age, condition or type of disease, we would not save more than one out of every ten or twelve. Many physicians select their cases; indeed, I know of some who *will not* operate upon a child under three years, and of others who will not operate upon diphtheritic cases, on account of the known fatality occurring after tracheotomy in these cases.

In regard to the difficulty of performing intubation, I would say, that any of you who attempt the operation upon a child without practice upon the cadaver, will certainly be sorry for it. I have known of four physicians who have failed completely. In regard to the patient to whom the last speaker referred, the young lady with the tube in her stomach, that case I am afraid was not in my record. I unfortunately, or perhaps fortunately, did not secure the patient.

Dr. Parkes has stated that after tracheotomy, if he were able to remove the tube in less than six days he would have concluded that there could have been no membrane within the larynx, and that if he had waited a few days longer, the patients would have recovered without the operation. May I be pardoned for feeling that the natural inference would be, that in these cases of intubation, because the tube has frequently been removed on the third, fourth, or sixth day, there could have been no membrane present, and that the operation was unnecessary? In reply, I would state that in every case coming under my observation, false membrane has been expelled when the tube was introduced. The reason why the laryngeal tube can be removed earlier than the tracheotomy tube is that more or less membrane is detached when the tube is first introduced, and second, the pressure of the tube and the frequent coughing assists in dislodging the membrane; while after tracheotomy little or no air passes through the larynx until after the removal of the tube, and there is nothing to cause the dislodgment of the membrane.

In regard to feeding the patient. Many of my patients have taken abundance of nourishment without difficulty. Occasionally, however, there will be one that will not take a sufficient amount. It will depend a great deal upon the size of the tube. If we use a tube larger than is appropriate for the age of the patient, it will not always fit perfectly into the cavity of the larynx, and consequently the epiglottis will not close accurately over it. In a case such as Dr. Strong has referred to, where the membrane is pushed down ahead of the tube, the trachea forceps would be very useful in removing it.

There are a great many dangers from tracheotomy that are never met with from intubation; but we rarely hear of them. I have learned of one physician who attempted a tracheotomy on a child four years old. Cutting down hastily, he severed large blood-vessels, and losing his head at the sight of the copious hemorrhage, at once sewed up the wound, while the child, almost with his last breath, wanted to know if they were going to cut him any more. Another physi-

cian, in cutting down hastily in order to open the trachea, missed it, and accidentally severed the carotid artery. Indeed, the history of tracheotomy is replete with horrors, but we do not hear of them. In the hands of experienced surgeons, who are cool and collected, the operation may be a simple and safe one; but in the hands of the inexperienced and the nervous, performed, as it frequently is, in the dead of night, it then becomes a formidable, yes, a dangerous procedure. Intubation, on the other hand, can be performed quickly, in a very few seconds, and without the dangers attendant upon tracheotomy.

THE BALTIMORE ACADEMY OF MEDICINE.

Nidinized Platina Needles.

Dr. J. J. Chisolm exhibited a series of needles of various sizes, the invention of Dr. Genese, of this city, a description of which is here given in a note from the inventor.

They are made with platinized gold head, hardened under hydraulic pressure. This needle can be made as dense as steel, but will be found to work better, if the temper is below spring steel. It will pass through tough tissue easily, and cannot be broken, while the advantage of bending, if required, may be found of great service in some cases. This needle will pass through cartilage or dense cicatricial tissue. If irridium is added in the construction of this needle, it will be so hard that steel can be cut with it. This needle can be made of any shape or size, and it is indestructible under the pressure of the forceps or the action of acids. The eye of a needle is the part hardest to clean; this needle can be cleaned with nitric acid, thus making it a somewhat antiseptic needle.

Dr. S. C. Chew reported an interesting case of

Opium Poisoning.

He was called in consultation to see the patient, a lady who had been suffering from a severe attack of erythema nodosum, for the relief of which she had been getting a quarter of a grain of sulphate of morphia each night for four nights. On the fourth night she became comatose, a weak, irregular pulse set in, and a Cheyne-Stokes respiration appeared. The weak, irregular pulse the doctor considered as contra-indicating poisoning by opium. She was at the time supposed to be beyond relief. Hypodermic injections of brandy and tr. of belladonna were, however, ordered, but gave no relief. At about 5 o'clock on the morning following she was apparently past all aid, but as a last resort the attending physician gave her a hypodermic injection of tr. of belladonna alone of about twenty-five minims. To his surprise she began to rally, and by 9 o'clock of the same morning she was out of danger.

Morphia Taken for Quinine—Mercurial Inunctions for Lice.

Dr. F. T. Miles related a case of a man who was poisoned by taking morphia for quinine, and when seen, was apparently so near dead that therapeutic aid was considered useless. The patient recovered without any treatment whatever. The doctor has never seen a patient die during the Cheyne-Stokes respiration.

Dr. Miles referred to a case of a young man, supposed to be syphilitic, who had become paralyzed. The man was completely paralyzed; there was dribbling of urine, bed-sores, and semi-unconsciousness. He was in a most disgusting condition, being filthy, and in the hairy portions of his body infested with lice. Mercury was ordered internally for the syphilis and mercurial inunctions for the lice. The man made a rapid and complete recovery, which the doctor attributes to the rapidity with which his system was brought under the influence of the mercury, not so rapidly when given by the mouth as when rubbed into the surface—the object thus obtained was not intentional, as the inunctions were ordered, as stated, for the lice, but the result certainly suggests a valuable means of getting the rapid action of mercury.

Dr. J. J. Chisolm related a case of

Otorrhœa

that he had been called in consultation to see. The patient was in a very precarious condition. He was in a semi-comatose condition, and was at times unconscious. The mastoid region was painful, but not swollen. Pus oozed from the ear. There was aphasia, but no paralysis. He decided to open the mastoid cells, but upon a second consideration, as the patient was apparently moribund, concluded to try the effects of a large blister to the nape of the neck extending well down over the shoulders. The effect was pronounced; recovery was complete, and the patient is now in good health.

Stated meeting held June 1, 1886.

The Executive Committee reported favorably upon the thesis presented for admission by Dr. Robert T. Wilson, and he was accordingly elected to membership of the Society. Under the heading of "Relation of Cases,"

A Singular Coincidence in the History of Cancer.

Dr. J. J. Chisolm related a singular coincidence that recently came under his observation. It was a case in which he was called upon to amputate a cancerous external ear from an old man æt. 80. The coincidence rests in the fact that this man had had two wives, both of whom had had cancer, and both of whom had died as a result of the operation. Dr. Chisolm's patient, however, is still living.

Enucleation of the Eye-ball in an Infant.

Dr. J. J. Chisolm related the history of a patient two months of age, upon whom he had done the operation of enucleation of the eye-ball for intra-ocular trouble. The patient recovered. This is the youngest subject upon whom he has ever performed this operation.

Dr. J. Edwin Michael, in answer to a question by Dr. Miles, said that it had been his experience that young children stand the strain of operations to which they are sometimes subjected remarkably well.

Dr. G. Lane Taneyhill two years ago amputated a terribly crushed leg from a boy two years old. The patient suffered only a moderate degree of shock, from which he recovered entirely. The boy is now in excellent health.

Deficiency in Both Lower Eyelids.

Dr. J. J. Chisolm spoke of a case of a deficiency of both lower eyelids, the result of cicatricial contraction from two scars on either side of the nose. The scars were the result of operation for the closure of a very high degree of double hair lip. The fissures extended almost to the inner canthus of each eye, and back through the bony portions of the face there being an absence of the intermaxillary bones.

Restoration of Sight by a Fall.

Dr. G. Lane Taneyhill had recently a patient, a lady æt. 65 years, who had fallen down stairs striking upon the right supra-orbital ridge, causing laceration, ecchymosis and a considerable degree of hemorrhage. The patient claims to have been born absolute blind in her right eye. One week after the accident, while the doctor was dressing the wound, she suddenly exclaimed that she could see. Upon examination, he found that there was perception of light, and that when held in certain positions she could count fingers. There is apparently no lens present, but there is a calcareous condition of the capsule with a superior synechia. He thinks the explanation for the sudden transition, is that in the fall there was a displacement of some of the opaque media, thus making an opening for the passage of light.

Dr. J. J. Chisolm, notwithstanding the evidence of the woman's absolute blindness, don't think she was ever without appreciation of light. Absolute blindness means atrophy of the optic nerve, and he is acquainted with no means by which an atrophy of the optic nerve of sixty-five years' standing could be restored to a functioning condition. He thinks her so-called blindness only a matter of contrast.

Danger of Atropia in Plus Tension.

Dr. Herbert Harlan made some remarks in which he wished to call attention to the danger of instilling atropia into an eye with plus tension. He said he recently had a case of choroidal atrophy that gave nothing to suggest a plus tension, nor any glaucomatous formation. Wishing to demonstrate the atrophy more clearly to his class he dilated the pupil with a few drops of atropine solution. On the following morning the fundus and transparent media were opaque and cloudy, and the eye was very painful. An eridectomy resulted in complete relief. But the case has impressed itself upon his mind, and forms the substance of these remarks in which he wishes to caution others against the use of atropine until the tension of the eye has been carefully tested and glaucomatous trouble is absolutely excluded.

Dr. J. J. Chisolm said it was not uncommon for acute glaucoma to be set up by the careless and injudicious use of atropia.

Dr. Robert T. Wilson then read his admission thesis upon

Ovariotomy, with the History of a Case.

DISCUSSION.

Dr. B. B. Browne said that in his practice he had substituted irrigating the abdominal cavity with warm water, carbolized, for sponging, as it subjects the abdominal viscera to less violence. His results have been very favorable.

Dr. J. J. Chisolm then read a very interesting paper upon

A Complete Revolution in the After-Treatment of Cataract Operations.

The method had been suggested to him by Dr. Michel, of St. Louis, whom he had seen at the last meeting of the American Medical Association. It was brought before the Section on Ophthalmology, but did not meet with their approval.

Dr. Chisolm, however, decided to make a

trial of the plan suggested, and his results have been so favorable that he has now discarded entirely the old method of bandaging and incarceration of the patient in a dark room, for the new method of simply closing the eye in its natural position and retaining it so by a bit of light adhesive plaster, and allowing the patient the liberty of lighted rooms.

The advantages claimed are first, that a more uniform pressure can be obtained through the natural muscularity of the lids than by any artificial padding that might be employed; and second, that patients who have not been shut out from the light are less sensitive to its action when the eye is sufficiently healed to permit of its exposure, than those who have been retained in darkened rooms.

Moreover, it admits of a means of entertainment for the patient for they can then have their friends read to them, a privilege denied patients treated under the old plan.

The new method recommends itself especially because it possesses in a most limited degree any procedure that alters to a great extent the normal relations of the patient. The method in detail is simply this, after the removal of a cataract or the performance of an iridectomy, the eyes, if a cataract, the eye, if an iridectomy, is closed in its normal position, and a bit of isinglass plaster about two and a half inches long by one inch wide is then rendered flaccid by immersion in some germicide fluid and is neatly applied to the surface of the closed lids. When dried, this forms a close, firm band. The patient is then allowed the full liberty of his room and in every case thus far operated upon the results have been uniformly good.

The doctor has treated eighteen cases (fourteen cataracts and four iridectomies) in this way, and many of them go out from the hospital into direct daylight without even as much as smoked glasses to protect them, and they complain of no photobia nor lachrymation. On the sixth day, when the plaster is removed, the eye stands the light better than it did on the tenth day under the old method. The length of time required for complete healing of the eye operated upon is, on an average, about two weeks, but the most of the eighteen cases could have left the hospital on the tenth day.

Under the head of miscellaneous business, this being the last meeting of the present session, the following officers were elected for the ensuing year:

President.—Dr. P. C. Williams.
Vice-President.—Dr. Alan P. Smith.
Treasurer.—Dr. G. Lane Taneyhill.
Secretary.—Dr. C. C. Bombaugh.
Executive Committee.—Dr. J. J. Chisolm, Dr. J. Edwin Michael, and Dr. A. B. Arnold.

The Society then adjourned to meet the first Tuesday evening in October next.

Editorial Department.

Periscope.

Peroxide of Hydrogen as a Therapeutic Agent in Diseases of the Eye.

Dr. J. Herbert Claiborne thus writes in the *New York Med. Jour:*

Recently much has been written in regard to the use of the peroxide of hydrogen in cases of purulent middle ear inflammation.

Bearing in mind its bleaching properties and presuming that the benefit alleged for it in such cases was due to these properties, it occurred to me that, in the form of a weak solution, it might be of advantage in catarrhal inflammation of the conjunctiva.

Experimentation was made in a number of cases with quite uniform results, which are appended below.

On the instillation of two drops of a ten per cent. solution into the conjunctival sac in chronic catarrh, the following was observed:

The patient invariably started as the drops fell into the eye; that portion of the conjunctiva which was bathed in the drops became blanched and presented a "washed-out" appearance in from half a minute to one minute after instillation; this condition lasted at least five minutes; immediately after introduction the bulbar conjunctival vessels became constricted; this condition yielded to marked distension in a few minutes; bubbles rose to the surface of the fluid, and some remained clinging to the bottom

and sides of the sac; twenty to twenty-five minutes after the instillation the eyes presented an irritated appearance, the bulbar vessels remaining still distended and the palpebral conjunctiva equally as red, if not redder, than before.

The patients complained irregularly of stinging immediately after the introduction, which lasted on an average from one minute to a minute and a quarter. Twenty to twenty-five minutes after the first instillation they invariably stated that their eyes felt better and more comfortable.

In acute cases the same was observed, save that the bulbar vessels became immediately distended after the instillation without apparently becoming smaller in half an hour. No exact difference can be drawn between the effect of a ten and a five per cent. solution, nor between these and a one per cent. solution, save that with the latter the stinging is less and usually lasts only half a minute.

Instillations were made also directly upon the cornea; there was no change in its appearance; the stinging was no greater, and no local anæsthesia occurred under half an hour's observation; there was no effect upon the pupil. The instillations were made every third day at the clinic.

The patients were instructed to use no other form of treatment; they invariably returned with the eyes in a less inflamed condition.

Encouraged by the ultimate result, I was bold enough to prescribe a five per cent. solution for one patient with acute follicular conjunctivitis, and to direct him to put two drops into each eye morning and night. He returned on the third day with the eyes much worse. He complained of severe stinging on the introduction of the drops, which, however, soon passed away.

The bulbar vessels were intensely congested and did not yield entirely to several drops of a four per cent. solution of cocaine.

In the light of the foregoing observations, I do not feel justified in advising the use of the peroxide of hydrogen in eye diseases, and, although no alarming reaction followed its use in any case, I gladly relegate to others its employment in the eye.

The Effects of Atropine and Whisky in Carbolic Acid Poisoning.

Dr. S. E. Bascom, of Salt Lake City, reports in the *Philadelphia Medical Times* the following very interesting case of carbolic acid poisoning treated successfully with atropine and whisky. He says that on May 4 he assisted Drs. Fowler and Potter "in a perineorrhaphy, the laceration involving the sphincter ani and about two inches of the recto-vaginal wall."

"The patient, Mrs. L., a lady 22 years of age, well nourished, quite obese in fact, had been married three years, but had given birth to but one child, eighteen months previous to operation, at which time the laceration occurred. The results of the operation were perfect, and on May 12 we visited our patient for the purpose of removing the sutures. When within a short distance of the house we were met by a sister of the patient, who informed us that the nurse, by mistake, had given the 'wrong medicine,' and on reaching the house we were told that the nurse had intended giving the patient potassium bromide, but instead of this had given a tablespoonful of pure carbolic acid. The mother seeing a mistake had been made, seized the spoon and placed it to her lips to make certain as to what had been given; the result was considerable excoriation of lips and tongue. When we reached our patient, within ten minutes of the time when the dose had been taken, she was unconscious, cyanotic, almost pulseless, respiration rapid and irregular, with mucous rales throughout both lungs. The mother had given her several ounces of olive oil. We felt the case to be hopeless, but, more to satisfy the friends than from any expectation of favorable results, we administered by hypodermic injection two minims of sol. atropiæ (gr. iv to ℥j.) and two drachms of whisky. Within ten minutes of the time the injections were given the pulse and respiration had improved decidedly, and the constitutional effects of the atropine were marked. In half an hour the patient became conscious, vomited freely, with hematemesis. Milk was given in teaspoonful doses at short intervals. Injections of brandy were continued, and later in the evening another dose of atropia. No saccharated calcium was used in the case.

"By the afternoon of the following days Mrs. L. had so far recovered that we decided to remove the stitches, and, aside from the soreness of the mouth, some diarrhœa, and more or less pain in the stomach and intestines (which was easily controlled by morphine), no unpleasant symptoms manifested themselves. The carbolic acid was freely eliminated by kidnes and skin, the discoloration of the urine and odor of the perspiration being noticeable for several days. Within three days the patient was sitting up, and is now entirely well."

Œdema of the Penis from Abnormal Coition.

Dr. S. T. Armstrong thus writes in the *Mississippi Valley Medical Monthly:*

In no work on genito-urinary diseases that has been accessible have I found any reference to œdema of the penis consequent to abnormal coition. While there may be a criticism on the lack of a definition, aside from Ovid (Elegy VII., T. III., Amores), and a few other classical authors, of normal coitus, yet the *lex non scripta* would indicate any departure from a certain standard.

The following case will explain itself:

J. B., negro, aged thirty-six, native of Alabama, was admitted to the U. S. Marine Hospital at this point on April 26, 1886, for œdema of the skin of the penis, extending almost to the pubes. He stated that on the evening of April 22 he had connection with a negress, she sitting on his lap facing him, and causing the friction. He stated the act caused no pain, and in fact he had indulged in this method of sexual congress before. On April 23 his penis commenced to swell, and when admitted to the hospital measured six and a quarter inches in circumference at the glans and five inches at the pubes. The prepuce could not be retracted on account of the extensive œdema. Lead and opium lotion was applied without advantage in reducing the œdema, and on May 1 unguent. hydrarg. was rubbed in freely; this treatment being continued daily, the skin of the penis gradually returned to the normal condition. He was discharged, recovered, on May 11, eighteen days after the œdema commenced.

This history was narrated to a large number of physicians, none of whom had ever known of such a case except Dr. R. M. Pate, of Memphis, who kindly gave me the notes of the following case which he had treated:

W. P. S., aged thirty-two, white, treated in July, 1882, for œdema of the penis following coition, the woman sitting on his lap, as in the former case. The prepuce and a small portion of the skin of the penis just posterior to the glans was enormously swollen. The treatment was by free incision into the œdematous skin, immersion of the organ in hot water, and local applications of carbolized glycerine and water. The case recovered in eight days.

The cause of the œdema can only be explained by traumatism during the copulanation. The treatment pursued by Dr. Pate is preferable, as the patient recovers in the shortest time, though care would seem requisite to prevent sloughing at the points of incision.

Retraction of the Penis.

Dr. Thos. F. Raven thus writes in the *Lancet*, August 7:

I should have published the following singular case some two years ago had I not feared that the strange details would be received with incredulity; but since a similar but more strongly marked example of the same condition has recently been recorded by Dr. Ivanoff, in a Russian medical journal, I do not hesitate to bring my own experience forward.

A. B., a healthy, steady single man, aged twenty-seven years, shortly after he had gone to bed one night, felt a sensation of cold in the region of the penis. He was agitated to find that the organ, a fairly developed one, was rapidly shrinking, and was, he thought, finally retiring. He at once gave the alarm, and I was hastily summoned from my bed to attend him. I found him highly nervous and alarmed. The penis had almost disappeared, the glans being just perceptible under the pubic arch. The skin of the penis alone was visible, and looking as it does when the organ is buried in a hydrocele, or, in an extreme degree, as it does after death by drowning. I reassured him, and gave him some ammonia, and found next day that the natural state of things had returned, but he remained weak and nervous for some days. He could give no explanation of the occurrence, and the unnatural condition has never returned. The circumstances of this care were not of so distressful a character as those related by Dr. Ivanoff. In his case the penis had bodily disappeared, and was captured only after prolonged manipulation. Even then the patient seems to have distrusted its tendency to remain in its natural position, for he had tied a string around it above the glans, in order that it should not again escape him. In this instance, too, the result was satisfactory, but the tendency to retraction was not finally subdued until the patient had been six days under treatment. He was a peasant, aged twenty-three, a married man with a family.

Resection of the Rib for Gangrene of the Lung and Empyema.

Dr. K. Snellen, of Zeist, Holland, having a case of pneumonia, which was followed by gangrene of the lung and empyema, aspirated, deferring opening up the cavity of the pleura for a few days. A fluctuating tumor being detected at the spot where the aspirator had been introduced, resection of the sixth rib, by the subperiosteal method, was performed,

four centimètres being excised. When the pleural cavity was opened, an immense stream of extremely offensive fluid came away. The cavity was washed out, through a male silver catheter, with a three per cent. solution of boracic acid, and afterwards with a one per cent. solution of chloride of zinc, the wound being covered with Lister's dressing. For the next two days, the patient's condition was very much improved, but, on the third day after the operation, the temperature rose to 104.2° Fahr., and erysipelas of the face set in, which extended over the head and neck, the patient succumbing on the eighth day after the operation. It seems uncertain whether the gangrene was the direct cause of this erysipelas. The writer is disposed to think that, in these cases, it is better not to resect very early, but to aspirate first, so as to relieve pressure on the lung, and then, after waiting a short time for the patient's condition to improve, to evacuate and wash out the cavity. German literature on this subject is scanty. Schneider, of Königsberg, had a successful case of resection of the rib for gangrene, but the latter was of traumatic origin, being due to a gun-shot wound, and, therefore, was less likely to be associated with so unhealthy a constitutional state as the present case, which was due to pneumonia. Dr. Snellen also suggests the practicability of repeated aspirations.

Removal of Callus by the Galvanic Current.

The *Medical Herald* says that Dr. Meyer, of Berlin, records the following case (*Deutsche Med. Wochenschrift*): A boy, thirteen years years old, had sustained a fracture of the upper arm. After a plaster-of-Paris bandage had been applied, the arm was in three weeks so far healed that the lower and upper arm stood at an angle of 80°, the wrist being tightly drawn up, and the fingers lying without power or motion on the hand. Attempts had been made in vain to produce extension. When he was brought to Dr. Meyer, the latter discovered on the inner side of the elbow-joint a callus that occupied a third of the lower arm, and had included the flexors of the fingers, thus depriving them of active and passive motion. On the application of the induction-current to the upper arm there was considerable movement in the muscles supplied by the radial nerve. When the ulnar nerve was brought under the influence of the current a slight movemont of the abductor pollicis was observable, while irritation of the median produced a tingling sensation down into the hand. The galvanic treatment was as follows: The arm was laid on a conductor of the size of an octavo sheet, and a small electrode was applied, partly to the median nerve and partly to the callus. Frequent voltaic alternatives were employed. After sixty applications the boy could stretch out his arm fairly straight, and the place of the fracture could now be plainly felt on the inner side of the upper arm. After ninety applications the callus was reduced one-third, the active movement of the elbow-joint was nearly restored, and that of the wrist considerably improved. After one hundred and eighteen applications the muscles generally were in so good a condition that there could be no reasonable doubt about the perfect restoration of the use of the hand. This, Dr. Meyer thinks, shows that of all means the galvanic current is the most intensely sorbefacient.

A Simple Method of Removing Wens.

In the *Northwestern Lancet*, July 15, 1886, Dr. Lauenstein's simple method of removing sebaceous cysts of the scalp is described. The skin over large wens of the scalp is often so thin that, in the commonly practiced method of extirpation with a free incision over the convexity of the tumor, the sac is often ruptured in spite of all care, and through collapse of the walls of the sac the separation of the skin is rendered difficult and protracted in a disagreeable manner. This accident, unless it is a case of inflamed wen, may be avoided with certainty by a simple expedient, which has recommended itself to him on account of the rapidity of its execution, and which will be readily appreciated by those to whom it often happens to be pressed for time, or who, living in the country, are obliged to operate without skilled assistants. After shaving and cleaning the neighborhood of the wen, he makes a radial cut, about one inch long, through the skin where it is separated from the capsule of the wen, for instance, on the back of the head at the lowest point of the base of the tumor; through this slit he introduces the slender handle of the scalpel used, or a similar instrument, between the skin and sac, more or less deeply, according to the size of the tumor. This is very easily accomplished, and then he makes several sweeping movements of the scalpel-handle to the right and left, thereby separating with ease the sac from the skin. The elasticity of the skin allows almost the whole circumference of the wen to be separated in this way in a few seconds. He then cuts, with one snip of the scissors, the skin over the crown of the tumor as far

back as is necessary, and shells it out whole from its seat. There is often no bleeding, because of the division of the vessels of the sac by a blunt instrument. The rest of the treatment—sutures, drainage—is not affected by this procedure; nevertheless, he adds that any crushing or tearing of the edges of the wound is completely avoided.

Inoculation of Intermittent Fever.

Dr. C. E. Caldwell thus writes in the *Cincinnati Medical Journal:*

Blood was inoculated from "intermittent patients" on two healthy men, the following conditions having been complied with:

1. The place where the experiments were made was free from malaria.

2. The persons inoculated from were free from any other disease, especially syphilis.

3. The persons inoculated were willing.

4. The temperature of the persons inoculated was taken during a considerable period before the experiment, and showed no elevation.

The following results were arrived at:

1. The fever is inoculable by means of blood taken during an access.

2. The fever thus acquired differs from that acquired in the ordinary manner, by its irregular course.

3. After a number of attacks occurring singly or in groups, these developed in one case on the twelfth day, in the other on the twenty-fifth day, a comparatively regular quotidian, expressing the type of the source of infection.

4. The intensity of the disease was such in one case, on the nineteenth day, temperature was 105.6° F., in the other, on the twenty-eighth day, fever persisting for twenty-four hours, that they must be broken by a large dose of quinine.

5. The attacks occurred, with but few exceptions, in both persons at the hour of inoculation, 3 p. m., or reached their acme at this time.

6. The time of incubation would be hard to settle, owing to the isolated and unequal occurrence of the first attacks. The first fever motion occurred in one case on the seventh day, in the other on the twelfth day, the severe sequences of attacks in one case on the seventeenth day, in the other on the twenty-fifth day.

Trophoneurosis of the Skin Caused by Injury of the Median Nerve.

Before the American Dermatological Society, Dr. G. H. Tilden, of Boston, reported the case of E. F., fifty-five years of age, who had been wounded in the wrist by a circular saw four months before coming under observation. Three or four days after the infliction of the injury there was loss of the tactile sense, with a feeling of numbness in the last two phalanges of the fore and middle fingers. This had continued and steadily increased. Three weeks after the accident a bulla had appeared upon the terminal phalanx of the middle finger. Similar lesions had developed from time to time upon the last two phalanges of the fore and middle fingers. The bullæ had appeared every two or three weeks, and had not been accompanied by any subjective sensation. Six weeks' treatment with the faradaic current had caused decided improvement in all the symptoms. During this period only one bulla had formed. He had then stopped treatment and returned to work. Three weeks later all the former symptoms had suddenly returned. The patient had since disappeared.

The treatment of these cases consisted in the use of electricity and the application of blisters over the seat of injury. A last resource was to cut down upon the affected nerve and endeavor to relieve any constriction or pressure upon the nerve which might be found. If no such condition was detected, resection of a portion of the nerve might be advisable, since complete section was not apt to be followed by spontaneous trophic changes, and since it had been found by some observers that resection of a portion of the affected nerve was sometimes followed by the arrest of the trophic changes.

Bichloride of Mercury for Consumption.

The *Virginia Medical Monthly* for August, says:

"We have for some time been using corrosive sublimate with such marked advantage in the treatment of tuberculosis of the lungs, in a manner so much like that spoken of in the subjoined extract from July number, 1886, of *Progress*, that we had intended before this to make note of the fact. *Progress* does not tell us to whom to credit the following striking illustration of its value in tuberculosis: S. T. M., aged 38 years, came October 23, 1885, in a very feeble and emaciated condition, suffering from severe dyspnœa, hoarseness, frequent chills, followed by high fever, and colliquative sweats. Examination showed extensive infiltration of the epiglottis and the walls of the larynx. The vocal cords were concealed behind the

swollen tissues above. The cough and expectoration seldom ceased more than five minutes at a time during the entire day. The sputum was so rich in tubercle bacilli, that mounted preparations of it were used as samples for illustration in teaching. This man got a spray of the bichloride of mercury, prepared as follows:

℞.	Hydr. bichloridi,	gr. ij.
	Aquæ destillatæ,	Oj.
	Sodii chloridi,	ʒj.
M.	Ft. solutio.	

"He was ordered pills of the bichloride gr. $\frac{1}{10}$ each, one before each meal and at night, and a pill composed of assafœtida gr. iij, and ext. nux vomica gr. $\frac{1}{4}$, to be taken at the same time. In six weeks he was walking the fields five or six miles daily, hunting game. He was married last January, and is now out West."

The Effect of Sea-bathing on the Ear.

Dr. Sexton thus writes in the *Med. Record*, August 28:

Persons may nearly always escape the injury to which the ears are liable in bathing, by the observance of a few simple precautions. They should not expose the face or ear to incoming waves, especially such as are just "breaking" at the height of the head—*i. e.*, they should be on their guard not to be caught unawares. In floating upon the back, water is liable to trickle into the canal of the ear, and in diving it also enters easily. Such a result may be prevented by wearing non-absorbent cotton or sheep's wool in the opening of the ear.

On coming out of the bath no time should be lost in wiping out any water that may remain in the canal, and drying the parts; this may safely be done by rolling a small bunch of the fibres of absorbent cotton-wool on the end of a "parlor" match, from which the ignitable portion has been burned. The cotton should project well over the end of the stick to protect it, and to form a brush resembling those made of camel's hair. This brush may, with care or after proper instruction, be carried by the bather himself down into the ear for an inch, or until felt impinging on the drumhead; the use of one or more will remove all moisture, and probably prevent any further injury liable to occur from the presence of such an irritating fluid as sea-water.

A Wandering Tapeworm.

Dr. W. Davidson Bidwell, of Leavenworth, Kansas, writes to the *Medical Record* that a short time since a lady from the country brought him her boy, three years of age, with the account that he had passed several pieces of tapeworm during the past two months, and had become feverish and sickly. At bed-time a dose of castor oil was given the boy, and the next morning fifteen minims of oleo-resin of male fern in five-minim capsules, at intervals of one hour, another dose of oil being given in the afternoon. That evening the child passed a very long worm. A piece about a yard long became detached from the rest, and this piece, which tapered nearly to a point at one end, moved off, pointed end first, across the floor some six feet, and had climbed up the smooth side of the wall a distance of two and a half feet before it was discovered. The rest of the worm was noticed to wriggle some, but did not attempt to crawl away. During the two months that the child was passing portions of tapeworm, large numbers of pinworms were noticed almost daily in the evacuations. Dr. Bidwell asks whether such motions of a tapeworm outside of the body are often observed, and also whether it is common for the two kinds of worms to be associated?

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Two strong appeals for a higher standard of medical education appear almost simultaneously. One is by Dr. H. Genet Taylor, and was read before the New Jersey State Medical Society; while the other was read before the University Convocation at Albany, by Dr. William H. Watson, of that city.

——A serious arraignment of some of the theories of our common school system is contained in President E. A. Wood's address before the Medical Society of Pennsylvania. It has been issued in pamphlet form with the title "Heredity and Education," and should receive the attention of educators.

——The article on "The Adirondacks as a Health Resort," contributed to this journal by Dr. George E. Shoemaker, has been republished in neat form.

——A useful paper, with discussion, on "Electrolysis in Gynecology," by Dr. Franklin H. Martin, of Chicago, has appeared as a neat reprint, and contains many valuable suggestions.

——Dr. L. S. McMurtry, of Danville, Ky., in a reprint before us, narrates a case of ovariotomy, and adds some suggestive comments upon it.

——The value of intubation of the larynx as a substitute for tracheotomy is set forth in a reprint by Dr. E. F. Ingalls, of Chicago.

——"Meconeuropathia" is the name given by Dr. C. H. Hughes, of St. Louis, to the peculiar nervous symptoms which follow the excessive use of opium. He describes it in detail in a reprint of 14 pages.

——The curious affection known as "Trigger Finger," is described with illustrative cases by Dr. George W. Jacoby, of New York, in a reprint before us.

——The London Society for the Abolition of Compulsory Vaccination, forwards a 16mo. volume of about 150 pages, inveighing against vaccination in general, and its compulsory enforcement in particular. It is one of the remarkable sights of the age, this perversity in opposing the most beneficial discovery ever made in medicine.

BOOK NOTICES.

The Refraction and Accommodation of the Eye, and their Anomalies. By E. Landolt, M. D. Translated by C. M. Culver, M. D., with 147 illustrations. 8vo., cloth, pp. 600. Price, $7.50. J. B. Lippincott & Co., Philadelphia, 1886.

As a work on the physical properties of the eye there is probably none which is more exhaustive than the one before us. The latest methods of investigation are set forth with remarkable perspicuity and fullness, and the immense clinical importance of studying and treating the eye as an optical instrument is fully vindicated.

The text is divided into three parts: The first is occupied with the strictly physical portion of the subject, as the properties of lenses, the laws of reflection and refraction, the dioptric system of the eye, etc.

The second part is entitled "The Theoretical Portion;" it treats of the refraction of the eye, the various methods of determining its refraction and accommodation, and astigmatism.

This is followed by the third and last part, devoted to clinical considerations. In this we find discussed the various anomalies of refraction, as hyperopia, myopia, defective accommodation, etc. Presbyopia is scarcely recognized by the author as a separate topic, as he believes that the condition so-called properly comes under some of the other divisions which he has instituted.

The book is well written and well translated, and should receive a careful reading from every one who would make himself master of this important specialty.

A System of Practical Medicine by American Authors. Edited by William Pepper, M. D., etc., assisted by Louis Starr, M. D. Vol. v. Diseases of the Nervous System, pp. 1326. Philadelphia, Lea Brothers & Co., 1886.

This bulky volume contains a really enormous amount of excellent material. Its contributors are twenty-three in number, and but few of the leading neurologists of the country are notable by the absence of their names. It is fair to add that there are some, however, of the very first rank who are not represented.

This is the concluding volume of this national work, and both editors and publishers may be congratulated on the manner in which the undertaking has been accomplished. It stands, and it long will stand, as a striking monument to the high culture of the American profession, and the contents of these large tomes is throughout of an order of merit which would redound to the credit of the profession anywhere in the world. It is in strong and favorable contrast to the ponderous, theory-laden tomes of Ziemmsen's *Cyclopædia*, and prove, what we have often maintained in this journal, that in points of practical medicine we are far ahead of German and French writers, and little, if any, behind them in the theoretical and abstract investigation of disease.

Of the topics treated in this fifth volume we need only say that they cover the whole ground of diseases of the nervous system. We have a prefatory article by Dr. Seguin on general semeiology, followed by monographs on mental diseases, headache, vertigo, tremor, paralysis, chorea, tetanus, alcoholism, epilepsy, catalepsy, neurasthenia, disorders of sleep, athetosis, meningitis, neuralgia, etc., etc., by the contributors. All are discussed in a satisfactory manner.

——The eminent obstetrician, Dr. Späth, Professor of Midwifery in the University of Vienna, has retired on a pension; and Dr. Breisky, Professor in the University of Prague, has been appointed in his room. The chair vacated by Dr. Breisky has been filled by the appointment to it of Dr. Ludwig Bandl, Professor Extraordinary of Obstetrics in the University of Vienna.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE RELIGIOUS PROPRIETY OF ANÆSTHETICS IN CHILD-BIRTH.

The learned Dr. Mielziner, Professor of Hebrew in Union College, Cincinnati, discusses in a late number of the *American Israelite* the propriety of administering anæsthetics to women in childbirth. For is it not written in the book of Genesis that God said to the woman, "In sorrow (pains) shalt thou bring forth children?" And would not God be irritated to find out that Dr. Morton or Prof. Simpson, by discovering ether and chloroform, had entirely annulled His law, and had victoriously cancelled the punishment He had laid on women because Mother Eve gave Adam the apple?

We confess that the gravity of this view of the case had never impressed us before. But Dr. Mielziner informs us that devout ladies "have often refused to be placed under the influence of chloroform during childbirth" in consequence of this pious scruple. It is highly gratifying, therefore, to be able on the excellent authority of Dr. Mielziner to assure such tender dubitants that the ancient rabbis did not include this injunction among the 613 which are prohibitory in their nature; they looked upon it not as a command, but merely as a statement of what usually takes place. In fact, the Talmud mentions that certain "somnific drugs" were administered to criminals about to be executed, and doubtless this alleviation would have been extended also to women in travail, had their pains been considered worthy of notice by those wise men of old.

We feel greatly relieved at this decision, as we should not have liked to have been left in the predicament of having, on the one hand, either to baffle and disappoint Divinity, or, on the other, to allow parturients to suffer the agonies which we could so easily relieve.

MEDICAL NUMISMATICS.

Those who consider collectors of old coins and medals as harmless but useless monomaniacs, have little idea of how much of history finds its strongest and often its only support in just such collections. There are no relics of the past more valuable for certain important investigations than coins and medals. They reveal the condition of art, and preserve the names and figures of generations long obliterated.

Medicine itself can be historically studied from its medals and from evidence derived from coins, and we are glad to announce that this fruitful field is now under active culti-

vation by one of the most highly cultivated physicians of our country—Dr. Horatio R. Storer, of Newport, R. I. At a recent meeting of the Newport Historical Society, he stated that he is at work upon the history of medicine from a numismatist's point of view. As special collections in this branch are rare, any of our readers who possess medals or coins in any way illustrating medical events or distinguished physicians, or discoveries in our profession, should place themselves in communication with Dr. Storer, and aid him in his researches.

We have no doubt that the prosecution of this study will throw light on some of the dark corners of medical history, as it has upon the political and personal life of many remote ages and localities.

THE DANGERS THAT BESET PHYSICIANS.

There are many designing persons in this world, and it behooves us to be careful lest we, unwittingly, get ourselves into traps that hold us fast. The physician should be very careful in his intercourse with his female patients, for he should ever remember that the law most jealously guards the honor and chastity of a woman, and in this jealous guarding may sometimes bear heavily upon the physician who is not very discreet.

Let us suppose a case that may happen to any one. Let us suppose that an employer has reason to suspect that one of his female employees has become illicitly pregnant. He calls in a physician to determine the question. He says to the servant, "You must submit to this examination, or else I will discharge you." The woman perhaps replies, "I know that *physical* resistance is useless when two strong men say that I *must* be examined, but I do not give my consent to the proceeding." Were an examination made under such circumstances, we are inclined to believe that it would be legally construed as an assault.

The point we wish to make is that a physician always runs more or less risk when he examines a woman save in the presence of a third party, before whom she has clearly given her consent to the proceeding.

A GREAT MEDICAL EDITOR DEAD.

The medical profession throughout the world has been accustomed for years to recognize the *Lancet* as one of the greatest of medical journals. By years of toil, battling, and endeavor, it succeeded, many years ago, in reaching that pinnacle of editorial fame to which the ambition of the elder Wakley always aspired, and there, through the ability and devotion of the son of the great founder, it has continued to perch. The elder Wakley lived to see his creature a creator of sentiment and a power in the medical world, and then in the fullness of time he laid down the pen, to be taken up and wielded with equal vigor by his son. For more than a quarter of a century Dr. James G. Wakley has been the controlling spirit of the great *Lancet*, and now he too has passed from among us. It may be remarked as a somewhat curious coincidence that the great champion of the sword of America (Grant) and the great champion of the pen of England (Wakley), both were finally conquered by the same insidious and relentless foe, cancer of the tongue. Let us hope that Wakley has trained up some one to properly fill his vacant chair.

Notes and Comments.

Sudden Death from a Blow on the Testicles.

At a recent meeting of the Varna Medical Society, Dr. Ivanoff recorded the following rare case (Bulgarian *Meditzinsko Spisanïë*, June 20, 1886, p. 440). A man, aged between forty-five and fifty years, fought with a woman on the street. During the fight the woman dealt a violent blow on his genital organs. The man shouted, "I am dying!" staggered, and fell insensible. The author, who was almost immediately fetched to the spot by a policeman, found the patient lying on his back, motionless, pulseless, and breathless; his face, neck, and scrotum being very red. Not a trace of ecchymosis or any other sign of injury was detected anywhere in the man. Since there seemed to be heard a slight cardiac murmur, and a slight tremor to be felt in the carotids, Dr. Ivanoff without any delay resorted to artificial respiration. But neither forty-five minutes' manipulation nor electrization could establish the man's breathing. The congested parts soon became livid, and every sign of life extinct. At the post-mortem examination there were found only intense congestion of the meninges and brain, congestion of the lungs with numerous punctiform ecchymoses, accumulation of dark red fluid blood in the cardiac cavities, congestion of the stomach, liver, kidneys, and testicles. Everything else was quite normal. Basing this conclusion on all the facts as sketched above, the author stated (forensically) that

death followed from syncope, which had been brought about by sudden violent pain caused by a blow on the testicles.

Sulphate of Sparteine.

Hans Voigt, working in Nothnagel's clinic, has come to the following conclusions repecting the therapeutical action of the sulphate of sparteine. In small doses, the salt increases the efficiency of the cardiac contractions and raises the arterial pressure. The number of heart-beats is always increased. These effects are observed within an hour of the administration of the drug, and continue for twenty-four hours. The author recommends the suspension of the administration of the drug for some days, but it may be given for a week without risk. The remedy does not always regulate the rhythm of the heart-beats. Its action on the respiration is variable. Diuresis appears to take place in proportion to the improvement of the cardiac action. A beneficial sedative action is often obseerved. Headache, vertigo, malaise, and other objectionable symptoms, were but rarely met with as the result of the administration of small doses. The dose employed has been from one to four milligrammes. It will be remembered that in Sée's hands much larger doses (five to twenty centigrammes) were tolerated without cumulative or other objectionable effects.

An Anodyne for Use in Vesical Irritation.

Dr. W. P. Copeland, of Eufaula, Ala., writes (*Med. Record*): "In almost every community there are old men who suffer from enlarged prostates, accompanied with a chronic inflammation of the neck of the bladder, rendering them miserable sufferers and a care and anxiety to their friends and families. Having had the professional care of several of this class of cases, and dreading the tendency they so frequently acquire of the administration of opium for the relief of pain, I resorted to various washes for injecting the bladder, resulting in my adopting a solution of benzoate of soda, ten grains to one ounce of water, with twenty to thirty drops of the green tincture of gelseminum; this is warmed and injected by the patient through a soft rubber catheter, whenever the pain is severe, and the catheter withdrawn, leaving the medicine to be voided in twenty or thirty minutes; or where they are not able to pass anything from the bladder, the catheter is reintroduced and the medicine allowed to escape. My experience with this treatment has been so satisfactory that I cannot refrain from giving it publicity to the profession."

A Case of Probable Tuberculosis of the Skin.

To the American Dermatological Association Dr. Tilden related the history of a case occurring in a healthy-looking boy of two years of age, who had presented six or eight cutaneous lesions scattered over various parts of the body. These were of about the size of a split pea, slightly elevated above the level of the skin, and of a bright-red color, which disappeared entirely on pressure. They were hard to the touch, with borders of sensible infiltration. They had appeared within the previous five months, and had been very slow in growth. During the previous three months there had been failure in appetite and strength. In nearly all of the nodules there had ensued softening, with formation of pus, which had been discharged, and this had been followed by cicatrization. Four months later there had appeared in the left buttock a swelling which gave an obscure sense of fluctuation. In February the swelling in the buttock had increased in size, and there was more fluctuation in it. There was at this time sufficient outward curvature of the lumbar vertebræ to justify a diagnosis of Pott's disease. The author thought the most probable diagnosis to be tuberculosis of an unusual form.

Bismuth Subnitrate in Fœtid Perspiration of the Feet.

Vieusse (quoted in *Practitioner*, May, 1886,) draws the following conclusions:

1. Profuse perspiration of the feet, whether accompanied by pain or fœtidity, is easily cured by the application, with slight friction, of subnitrate of bismuth upon the diseased parts.

2. In opposition to the opinion generally held, according to which, the suppression of exaggerated perspiration may produce numerous accidents of metastasis, observation shows that the cure of this affection has not been followed by any unfavorable results, and that, if these are observed, they should be attributed to other methods of treatment hitherto employed.

3. In the cure of this disease, subnitrate of bismuth appears to exercise a purely local action, rendering the superficial cuticular structures firmer and more resistant.

4. In certain cases the remedy suppresses only temporarily the profuse perspiration of the feet, but causes the fœtid odor, as well as

the pain, which is the consequence of the exaggerated secretion, to disappear permanently.

Scarlet Fever and Scarlatiniform Eruptions Following Injuries and Operations.

Before the American Dermatological Association (*N. Y. Med. Jour.*) a paper on this subject was read by Dr. Atkinson, who first reviewed the literature of the subject referring to the cases on record. In many of these cases it was held that the affection had been a true scarlatina. In other cases the scarlatiniform rash was of septic origin. Various drugs which were frequently prescribed in traumatic cases would produce such eruptions, special reference being made to the cinchona alkaloids. The eruptions produced by these drugs were usually of an urticarial appearance, but they might be of a scarlatiniform nature.

Dr. Morrow said that the speaker had not mentioned the rash that often followed the use of antipyrine, which frequently simulated scarlatina. Again, carbolic acid and iodoform dressings would often produce rashes presenting the objective appearances of scarlet fever.

Paresis of the Respiratory Muscles following Diphtheria.

Dr. Rothmann (*Wiener Medizinische Wochenschrift*, June 12, 1886,) reports the case of a boy, seven years of age, who suffered from great difficulty of respiration following an attack of diphtheria six weeks previously. Inspection of the thorax showed the upper portion to be entirely without motion, and the lower ribs only rose and fell almost imperceptibly with the respiratory act. The epigastrium was also motionless, and none of the accessory muscles of respiration came to the aid of the little sufferer. The only way in which the child could increase his feeble expirations was by pressing with his little fists on the upper part of the abdomen. The treatment consisted in hypodermatic injections of strychnine, and the application of the induced current to the phrenic nerves and the abdominal muscles. After twenty applications of electricity, and the administration of about one-third of a grain of strychnine, the patient was cured.

Anæsthesia by Suggestion.

Dr. Pitres relates in the *Journal de Médicine de Bordeaux*, a case which well illustrates the power of hypnotic suggestion in producing anæsthesia. The patient was an hysterical woman, easily hypnotizable, who was suffering from a very painful phlegmon on the left thigh, following a hypodermic injection. The abscess was the seat of acute shooting pains, and could not be touched without causing the patient to scream. Dr. Pitres proposed to put the woman to sleep by hypnotism, then to order her to allow the abscess to be opened without feeling any pain, either during or after the operation, and finally to wake her up and make the incision. This was done as proposed; a dissection was made down upon the abscess, which was emptied of the pus, cleaned and dressed. During all this time the patient watched the proceedings with a smile, and expressed astonishment that the abscess could be opened without giving her the slightest discomfort.

Intra-peritoneal Injections in Acute Hemorrhage.

Rütgers (*Centralb. f. d. Med. Wiss.*, Aug. 7, 1886,) records the case of a woman who, as a result of post-partum hemorrhage, was in a state of profound collapse, and whose veins, after ligature, did not swell, so that no indication for the site of an intravenous injection was obtainable.

A solution of sodium chloride 90 grains, sodium hydrate 5 grains, and distilled water 34 fluid ounces, was accordingly introduced into the abdominal cavity by means of a trocar. After three days, during which abdominal pain and subnormal temperature obtained, the general condition was excellent.

It is evident, from this experience, that the absence of swelling in veins after ligature is no sure sign of actual death, and it is suggested that the method described may replace that of hypodermatic injection of water in Asiatic cholera.

Hemicyanosis.

M. Renaut (*Lyon Médicale*) gives the following summary of a case: In 1879 an attack of acute, poly-articular rheumatism, and development of mitral insufficiency, with slight stenosis; at the same time, the sudden appearance of a blue discoloration of the left side of the trunk and of the left leg. For six weeks, embarrassment of heart's action and very grave condition. The blue color, like that resulting from ligature of a limb, was strictly limited to the left side; it occupied the front and back of the thorax, the lumbo-abdominal region, and, after an interruption, was continued on the lower limb. It was almost uniform, but at a few

points deeper in color. There was no œdema, and no varix. The face and the neck were only slightly congested.

Renaut referred this hemicyanosis to a lesion of the intra-medullary vaso-motor centres.

Contagiousness of Variola at the Beginning of the Eruption.

Lancereaux reports three cases (*Bul. de l' Academie de Medecine*) occurring in his hospital service, in which small-pox was transmitted at the beginning of the eruption. From these facts he draws the conclusion that variola may transmit itself on the first, or at least the second day of the eruption, since the small-pox patient admitted by mistake into the hospital was transferred two days after the appearance of the eruption. This is, however, not the opinion commonly admitted. An English physician of great celebrity, Herberden, following the citation of Dezateux and Valentine, asserted that he was in possession of facts demonstrating that small-pox could not be communicated until after the second or third day of the eruption, and that persons who never had it might, up to this period, sleep with those who had it without risk of taking it.

Carbolic Acid in Whooping-cough.

Dr. Pick Coblentz (*London Med. Record*) highly recommends the inhalation of carbolic acid in whooping-cough. He says that while there may be doubt as to the nature of the virus, there is no doubt as to the presence of some kind of specific microbe. Of course, the efficacy of carbolic acid is due to its destructive power over this germ. His method of administering is as follows: A small ball of wadding is saturated with from fifteen to twenty drops of pure liquid carbolic acid, and is placed in a mask which must be worn all day if possible, or at least for eight hours, the wadding being renewed three times daily. The urine must be examined for carbolic acid. He thinks that the period of the cough is considerably shortened by the inhalation, and that long-continued inhalation produces no toxic symptoms. He asks for a further trial of this treatment.

Concussion.

A railway accident in which passengers are merely concussed may be the cause of a curious mixture of diseases. Concussion may be regarded as that form of shock which is independent of the conscious intervention of the individual concerned. Some of the passengers may suffer from symptoms that soon pass away; others will become the subjects of nervous diseases of long, if not permanent, duration. There can now be no doubt that organic, as well as functional affections, of the nervous system may arise as the outcome of an accident that causes concussion. The inflammation of the spinal cord that sometimes immediately follows concussion has a tendency to pass away; but this regressive quality is necessarily of slow kind, and may also be abolished in the presence of a syphilitic, gouty, or other pronounced diathesis.

The Proper Use of Antipyrine.

The *N. Y. Med. Jour.* says that Pavay (*Wiener Med. Woch.*) has employed this drug in a large number of cases, and gives some useful rules for its administration. He adopts a middle course in regard to the dosage. When the temperature does not exceed 103° F. he divides 31 grains into three powders, and administers one powder every half hour. If the thermometer registers 104°, three doses are given as before, each dose consisting of 15½ grains. With a temperature of 105° and above, he gives 62 grains in four doses, half an hour apart. It is seldom, the writer asserts, that the temperature fails to fall from 2° to 4°, and to remain lowered from six to sixteen hours. If for any reason the stomach will not retain the drug, it may be given by the rectum in doses of from 30 to 45 grains, or hypodermically in a fifty per cent. solution.

Taking the Temperature in Children.

A very ingenious and simple method has been proposed by Filatoff, in the *Archiv für Kinderheilkunde*, vol. vii., part 3, for expediting the troublesome process of obtaining the temperature in children.

He recommends that by the use of a previously-warmed thermometer the fall, and not, as is usual, the rise of the mercury be observed. In from one to two minutes the column is found to stop at a point which very closely approximates to the actual temperature of the patient. It is found that the higher the fever, the smaller is the error. Thus, at temperatures of from 103.1° to 104° F., the error does not exceed 0.2° F., while for lower temperatures it may reach 0.5° F. It is, of course, evident that a certain amount of care and skill is requisite in order that the precursory warming of the thermometer be neither insufficient nor excessive.

Value of Resorcin, Icthyol, and Lanolin in Cutaneous Diseases.

Before the American Dermatological Association, Dr. H. W. Stelwagon, of Philadelphia, read some notes on this point. In regard to lanolin, he said that in some cases as an ointment base this is superior to the ordinary fats in use. Where a simple protective action is desired, it is inferior to vaselin, cold cream, or lard. In chronic cases, where there is infiltration and a degree of penetration is the object, lanolin is especially valuable. The writer stated that according to Liebreich, a lanolium purissimum was now manufactured, in which the cholestrin ethers were absent. The main disadvantage of lanolin as now manufactured from sheep's wool is its strong sheepy odor. In a few acute and subacute cases of eczema, lanolin for some reason proved irritating. As a rule, however, it is bland and unirritating.

Tonics in Malarial Hæmaturia.

When fever has subsided, the quinine is left off, and the time has arrived for the employment of tonics, Dr. L. F. Calhoun (*Med. Herald*) knows of none better than the following:

℞.	Tinct. nux vom.,	ʒj.
	Tinct. mur. iron,	ʒiss.
	Elix. vitriol,	ʒj.
	Aquæ q. s. ft.,	ʒviij.

Sig.—A teaspoonful in water after meals, i. e., three times per diem. It should, of course, be taken through a glass or reed in order to prevent the vitriol from acting upon the teeth.

A second very good tonic is this:

℞.	Ferri et. quiniæ citratis,	ʒij.
	Strychnia sulph.,	gr. j.
	Tinct. columbæ,	ʒj.
	Syr. limonis,	ʒj.
	Aquæ rosæ,	ʒvj.

Sig.—Two teaspoonfuls in water three times a day.

Caffein as a Diuretic.

This subject is discussed by Dr. W. von Schröder in the *Centralblatt f. d. Med. Wiss.*, No. 26, 1886. He finds, as the result of experimental investigation, that the diuretic action of caffein, which is often very marked, is not due to any change in the pulse-rate or to increase in the blood-pressure, such as is produced through the agency of the vasomotor system, but is most probably brought about by a direct stimulation of the secreting elements of the kidney.

Similarly, Dr. A. Langgaard, in the same journal, No. 29, gives testimony as to the diuretic action of this drug, and agrees in every respect with v. Schröder as to the manner in which its action is brought about—that it occurs quite independently of any change in the blood-pressure, appearing even when the pressure is reduced to *nil.*

Oil of Turpentine in Scrofulous Ozæna.

Malacrida (*Centrlbl. f. Chir.*, July 17, 1886,) reports the case of a girl ten years old who had ozæna of long standing which had long been under treatment in vain. Taking a suggestion from the cure of old fistulous tracts with oil of turpentine, the author used this drug locally, and gave the patient a supporting diet. Cotton tampons moistened with a few drops of the oil were introduced into the nose. As they caused considerable irritation, those subsequently used were wrapped with dry cotton. A perfect cure took place in a week. Five other cases treated by the same method are mentioned, in none of which was the cure delayed longer than a month.

A Cure for Freckles.

Dr. Halkin's procedure (*American Practitioner and News*) is as follows: The skin being washed and dried is put on the stretch with two fingers of the left hand, and a drop of carbolic acid is applied exactly over the patch. When it dries, the operation is completed. The skin becomes white, and the slight sensation of burning disappears in a few minutes. The thin crust which forms after the cauterization should not be disturbed; it detaches itself spontaneously in eight or ten days, leaving a rosy coloration, which is soon replaced by the normal color of the skin.

Hippurate of Calcium in the Treatment of Cirrhosis of the Liver.

M. Dujardin-Beaumetz (*Union Méd.*, August 19, 1886,) employs the following preparation:

℞.	Hippuric acid,	6 drachms.
	Lime water,	16⅔ ounces.
	Syrup,	20 "
	Essence of lemon,	1 drachm.

Dose —A tablespoonful several times daily, so that the equivalent of one or two drachms of hippurate of calcium may be given.

Under the use of this drug the writer has observed a marked amelioration of the ascites attending cirrhosis.

The Treatment of Sick-headache.

Dr. W. Gill Wylie, of New York (*N. Y. Med. Journal*), has produced excellent rerults with the following method of treat-

ment: So soon as the first pain is felt, the patient is to take a pill or capsule containing one grain of inspissated ox-gall and one drop of oil of gaultheria every hour until relief is felt, or until six have been taken. Dr. Wylie states that sick-headache as such is almost invariably cut short by this plan, although some pain of a neuralgic character remains in a few cases.

Heat Destructive to the Comma Bacillus.

At a recent session of the Academy of Sciences in Amsterdam, Prof. Forster stated that he and Dr. van Geuns had found that the comma bacillus was destroyed by heating the substance containing it to 55° C. In their work "Les Bacteries," MM. Cornil and Babes state that the comma bacillus is destroyed by exposure to a temperature of 50° C. for few days; also that a culture of comma bacilli can be sterilized by slowly heating it to 65° or rapidly to 75° C.

Application for Use in the Eruption of Wisdom Teeth.

Delioux de Savignac (*Revue de Thérapeutic*, July 15, 1886,) has commended the following mixture as an application to the inflamed gums over wisdom teeth in the process of eruption:

Glycerole of starch,	ʒij.
Pulverized borax,	gr. xv.
Pulverized saffron,	gr. viij.
Tincture of myrrh,	gtt. x.

With this make gentle and repeated frictions of the gums.

Œdematous Laryngitis.

Dr. Mackern, Buenos Ayres, reports in the *Lancet*, May, 1886, three cases of œdema of larynx treated by scarification and external blistering, with uniformly good results. In case 1, the œdema arose from a syphilitic ulcer, and there was a slow development of the symptoms. In case 2, the laryngeal trouble was secondary to an erysipelatous pharyngitis, and came on suddenly. In case 3, the cause was obscure. In each case the œdema was in the ary-epiglottic folds and ventricular bands, and the true vocal cords were entirely hidden.

Another Remedy for Vomiting of Pregnancy.

Still another remedy for this much medicated condition has been found in the hydrate of cocaine. When everything else had failed, when hope had fled, and abortion seemed the only alternative, Dr. Holtz gave his patient a hypodermic injection of cocaine, and the vomiting ceased. The writer is happy to record the instance as one of the few in which cocaine has appeared to be good for anything except for local anæsthesia.

Peroxide of Hydrogen in Epilepsy.

Dr. B. W. Richardson recommends (*The Asclepiad*) this drug for more extended trial in epilepsy, and records some strikingly successful cases. It should be given in what is known as the ten-volume solution, one fluid drachm three times daily in half a tumbler of water, increasing the dose gradually to two or even three fluid drachms. To mask the metallic taste of the drug, a drachm of glycerine should be given with each dose.

Treatment of Diphtheria Complicating Scarlet Fever.

Dr. Heubner, of Leipzig, treats these cases by means of injections into the tonsils and gums of a three per cent. solution of carbolic acid. This should be done on both sides of the mouth and throat twice daily, with an instrument prepared by him for the purpose. Since H. has applied this method, the rate of mortality has fallen from thirty-five to thirteen per cent.

Sanguinarine Nitrate.

Reporting the results of his use of this drug in the *N. Y. Med. Jour.*, Dr. E. R. Shurly says that no special results follow the local use of this drug, but for internal administration in a certain class of cases it is highly useful as a stimulating expectorant. He has noticed no unpleasant effects of depression from it in doses of $\frac{1}{10}$ to $\frac{1}{4}$ of a grain in syrup.

Pilocarpine in the Treatment of Adenitis.

In the *Medical Record* Dr. Dourado recommends the treatment of chronic enlargement of the lymphatic glands by the injection of the salicylate of pilocarpine. In chronic parotiditis and in adenitis of the inguinal glands, the treatment was also successful.

Prescription for Alopecia.

Oil of sweet almonds and stronger liquor of ammonia, of each, one ounce; spirit of rosemary, 4 ounces; honey water, 2 ounces. Mix. This lotion is to be rubbed well into the roots of the hair and over the scalp, and

the head should afterwards be washed with clear, soft water—rain or distilled water, if possible.

A Russian Ointment for Articular Rheumatism.

Grinevitski (*Brit. and Col. Druggist*, July 24, 1886,) is credited with this formula:

℞.	Extract of aconite.	½	drachm.
	Mercury ointment,	1	"
	Hyoscyamus ointment,	½	"

News and Miscellany.

American Rhinological Association.

The fourth annual meeting will be held at St. Louis, Mo., October 5th, 6th, and 7th, 1886.

PROGRAMME.

OCTOBER 5TH—MORNING SESSION AT 10 O'CLOCK.

Roll Call.—Address of President, A. De Vilbiss.

Papers.

1. A Mixed Form of Atrophic and Hypertrophic Catarrhal Inflammation (heretofore undescribed), and its Treatment. By P. W. Logan, M. D., Knoxville, Tenn.

Discussion.

2. Thoughts Relating to the Naso-pharyngeal Tract. By J. W. Fink, M. D., Hillsboro, Ill.

Discussion.

3. Chromic Acid and Tri-chloro Acetic Acid in the Treatment of Hypertrophies of the Pharyngo-nasal Cavities. By Drs. J. A. Stucky and O. F. Brown, of Lexington, Ky.

Discussion.

Adjournment at 1 p. m.

AFTERNOON SESSION AT 3 O'CLOCK.

4. The Future of Rhinology. By Carl H. von Klein, M. D., Dayton, Ohio.

Discussion.

5. Necrosis of the Nasal Bones. By H. Jerard, M. D., East Lynne, Mo.

Discussion.

6. Oleate of Quinine in Nasal Catarrh. By Jno. D. Sympson, M. D., Bloomington, Indiana.

Discussion.

Adjournment at 6 p. m.

OCTOBER 6TH—MORNING SESSION AT 9 O'CLOCK.

Business Meeting.

I. Report of the Secretary and Treasurer. II. Report of the Librarian. III. Report of the Nominating Committee. IV. Report of other committees. V. Miscellaneous business.

Papers.—At 10 O'clock.

7. New Methods in the Treatment of Catarrhal Inflammation of the Nose and Throat, including Diphtheria, etc. By H. Marks, M. D., St. Louis, Mo.

Discussion.

8. Treatment of Pruritic Catarrh (Hay Fever). By. Thos. F. Rumbold, M. D., St. Louis, Mo.

Discussion.

9. The Use of Cocaine in the Treatment of Diseases of the Pharyngo-Nasal Cavities. By J. A. Stucky, M. D., of Lexington, Ky.

Adjournment at 1 p. m.

AFTERNOON SESSION AT 3 O'CLOCK.

10. The Importance of Constitutional Remedies in the Treatment of Chronic Catarrhal Inflammation of the Upper Air Passages. By H. B. Logan, M. D., St. Louis.

Discussion.

11. Treatment of Acute and Chronic Inflammation of the Superior Respiratory Passages. By W. G. Lipes, M. D., Toledo, Ohio.

Discussion.

12. Colds in Very Early Infancy; How Taken and How Prevented. By H. F. Hendrix, M. D., St. Louis, Mo.

Discussion.

Adjournment at 6 p. m.

OCTOBER 7TH—MORNING SESSION AT 10 O'CLOCK.

13. The Importance of Early Recognition and Treatment of Naso-aural Catarrh. By N. R. Gordon, M. D., Springfield, Ill.

Discussion.

14. Is Hay Fever (so-called) a Disease per se? By J. P. Matthews, Carlinville, Ill.

Discussion.

15. Scarification in Nasal Hypertrophy. By A. G. Hobbs, M. D., Atlanta, Ga.

Discussion.

16. New Instruments. By the Fellows.

Ballot for Officers for 1886–87, and their Introduction into Office. Announcement of the next place of meeting.

Adjournment.

OFFICERS, 1885–86.

President, A. DeVilbiss, M. D., Toledo, Ohio; First Vice-President, J. A. Stucky, M. D., Lexington, Ky.; Second Vice-Presi-

dent, Carl H. von Klein. M. D., Dayton, Ohio; Recording Secretary and Treasurer, P. W. Logan, M. D., Knoxville, Tenn.; Librarian, N. R. Gordon, M. D., Springfield, Ill.; Members of Council, R. S. Knode, M. D., Fort Wayne, Ind., Hiram Christopher, M. D., St. Joseph, Mo., E. F. Henderson, M. D., Los Angeles, Cal., H. Jerard, M. D., East Lynne, Mo.

A Danger from Public Baths.

An interesting case is recorded by Dr. Auburt, according to the *British Med. Journal*, in which blennorrhœa was communicated by means of a bath. A lady consulted him for her child, aged four years, who for some days had had an abundant vulvar secretion. The child complained also of pain and burning in passing urine. In relating the case, the mother stated that she herself had, for some weeks, been affected with a like discharge, and her husband with an urethral discharge. According to the lady's husband, this was due to drinking turbid wine; an explanation which, as it was satisfactory to the lady, was not questioned by the medical man. A microscopic examination revealed the gonococcus in the discharge from both mother and daughter. On further inquiry, it appeared that the child, three or four days before the appearance of the discharge, had taken a bath with its mother. No other possible source of infection could be thought of. In the same family there was another child which did not have the bath, and which escaped the infection. Professor Filippi, of Florence, commenting on this case (*Lo Sperimentale*, October, 1885), relates that during the previous year, fifty-five little girls were infected with vulvitis at the public baths of Santa Lucia at Florence. Some of the children also contracted severe purulent inflammation of the eyes. The only explanation of this outbreak was, that the contagion had been deposited in the water by some woman or child already infected. Professor Filippi goes on to remark on the hygienic and medico-legal aspects of the case. It is not always possible to make sure that people making use of public baths are free from every sort of infectious disease. Unless, therefore, the supply of water be undergoing constant renewal, the water ought to be changed for each person. The forensic aspect of the case is also important. When a child, with vulvar discharge, is brought for examination on account of a supposed criminal assault, the above-mentioned mode of infection ought to be borne in mind.

Milk Boiled and Unboiled.

Dr. M. Reichmann, in the *Deutsche Med. Zeitung*, draws the following conclusions from a number of elaborate experiments as to the digestibility of milk in the human stomach:

1- Boiled milk leaves the healthy stomach more rapidly than an equal quantity of unboiled milk.

2. The digestion of boiled milk is more rapidly accomplished than that of unboiled milk.

3. The coagulation of unboiled milk in the stomach is complete in five minutes.

4. The coagulation is not caused by the acid of the gastric jnice, and by the influence of a special ferment (milk-curdling ferment).

5. The acidity of the gastric juice is at first due almost solely to lactic acid, and later in the process of digestion to the presence of hydrochloric acid.

6. Hydrochloric acid first appears in perceptible amount 45 minutes after the ingestion of half a pint of milk.

7. For the first hour and a quarter after the ingestion of milk the acidity gradually increases, and then decreases until the milk has entirely left the stomach.

8. The curds of casein in digestion of boiled milk are much softer than in the case of uncooked milk.

The Beauty Trade.

The Duvals, of Paris, seem to have a talent for making themselves notorious. One has made himself famous throughout Europe by his restaurants; another some years ago got talked about by blowing out what brains he possessed at the feet of Cora Pearl, annoying that lady by messing her carpet. A third has just provided material for the Paris papers by an action he has lately defended against a Madame Lafitta, who sued him for some $360 for nostrums which she had supplied to him intended to make hair grow on his bald head. Madame Lafitta, it appears, had to wear a wig herself, but the fact does not seem to have depreciated her talents in the opinion of her clients. Her explanation was that she had no time to spare for cultivating her own hair. M. Duval, it appears, paid her 134 visits and used all her unguents, but at the end of the treatment his pate showed no signs of cultivation. He refused to pay more than a hundred francs as the value of the preparations, claiming that there had been an understanding that there was to be no pay unless a perfect cure was effected.

The judge supported his view of the matter, took his valuation as correct, sent Madame Lafitta and her balderdash to the right-about, condemning her at the same time to pay her own costs.

Liquor Statisiics.

Last year the British spirits retained for home consumption amounted to 26,609,488 gallons, 0.733 of a gallon per head of a population estimated at 36,325,115. The foreign and colonial spirits consumed represented 0.221 of a gallon per head, the quantity being 8,012,655 gallons. The amount of foreign wines consumed was 13,767,928 gallons, 0.379 of a gallon per head; of beer, 27,101,238, or 0.746 of a barrel per head; of tea, 182,408,830 pounds, equivalent to 5.022 pounds per head; of coffee, 32,660,320 pounds, 0.898 of a pound per head. These figures show a large falling off in the consumption of British spirits, nearly 2,000,000 gallons; a falling off of some 300,000 gallons of foreign spirits; and a slight decline in the consumption of foreign wines. Beer showed a slight increase in the total consumed, but not in the amount per head of the population. Nearly 20,000,000 pounds more of tea were consumed, and coffee also showed a slight improvement. These statistics must be highly encouraging to advocates of temperance, being an undoubted proof that their labors in the past have not been without effect.

Pen Picture of Lawson Tait.

Dr. W. O. Roberts, in the *American Practitioner and News*, August 21, 1886, says: "Mr. Tait is a much younger man than I had expected to find him. He is just forty-one years of age; he is about five feet nine inches in height, and weighs, I should say, two hundred and twenty-five pounds. His legs are short, body quite long and large; hands short and fat, but how nimble and dextrous! His hair is dark brown, slightly sprinkled with gray, and he wears it quite long. He has a full face with short side whiskers. His voice is pleasant and manly, and his whole make-up impresses you as belonging to a person of immense force. His manners are pleasing, and to friends cordial. I should say he was a good lasting hater. He is a native of Edinburgh, and was a pupil and very intimate friend of the late Sir James Simpson, to whose pictures he bears a striking resemblance. He does most of his operations before breakfast, and seems to be in a big rush during all the day."

The Influence of Foreboding in Disease.

In the *Asclepiad*, January, 1886, Dr. B. W. Richardson says that there are two kinds of forebodings—the fanciful and serious. False forebodings are presented by the persons of fanciful and flighty natures, who are really fond of contemplating risks, and who suggest anxiety one minute and laugh at them a few minutes afterwards. These forebodings have no serious importance. True or serious forebodings emanate from persons who are firm and thoughtful, who as a rule keep to themselves what is on their minds until something like a crisis has been reached, when they come to a conclusion to which they adhere, by which they are much influenced. These forebodings are a critical disease, and are bad; they have a direct effect on the physical powers; the heart's action is impaired, the digestion becomes affected, and there is a want of tone very much opposed to the restorative efforts. A wise plan is to take as little notice of these forebodings as possible, but to ridicule them is bad.

Consumption of Tobacco in Europe.

M. Paul Leroy-Beaulieu, in an interesting paper in the *Economiste Francaise*, gives the following figures, showing the quantity of tobacco consumed in the different countries of Europe, and the rate per 1,000 inhabitants is, according to him, as follows: Spain, 110 pounds; Italy, 128 pounds; Great Britain, 138 pounds; Russia, 182 pounds; Hungary, 207 pounds; France, 210 pounds; Denmark, 224 pounds; Norway, 229 pounds; Austria, 273 pounds; Germany, 336 pounds; Holland, 448 pounds; and Belgium, 560 pounds. In other words, while in Spain little more than 1 pound per head is consumed, nearly double that quantity is consumed in France, three times as much in Germany, four times as much in Holland, and five times as much in Belgium.

French Vital Statistics.

It was stated by M. Bertillon, in a letter recently delivered at the Hygienic Exhibition in Paris, that the movement of the population for the past year throughout France had been very unsatisfactory, the total number of births being 922,361, or, upon the average, 30,000 fewer than for the last fifteen years. Moreover, out of this total 74,118 were illegitimate, or rather more than 8 per cent. of the whole, this being the largest number of illegitimate births ever recorded. Upon the other hand, there had been a slight reduction in the number of

deaths, the total for 1885 being 836,897; but still the excess of births over deaths was only 85,464.

The Milk of New York.

Dr. Edson, of the Health Department, has been making an investigation of the milk brought to the city over the various railroads, and has found that in some instances it was diluted with as much as forty per cent. of water. On September 10, he made a report to the Board of Health of an inspection recently made by him of ten candy factories. At one of them he found a quantity of Venetian red, which is used to give color to low grade chocolates, and in another, some burnt umber, which is used in the coloring of Christmas toy candies. In none of the other establishments were any pigments found in use which are deleterious to health.

Separate Licensing Boards in Canada.

The *Canada Medical and Surgical Journal* says: "The advisability of establishing a Central Examining Board has now been fully entertained both by the Governors of the College and also by the general meeting of the profession. It will, therefore, doubtless come into force as soon as the necessary legislation shall have been obtained. The proposed composition is such that all interests seem to be fairly represented. The total number will be twenty, more than would be required, except for the absolute necessity for a double set of examiners, English and French."

Starvationists.

A community was started at Anaheim, California, several years ago, the principal feature of which was that only uncooked vegetable food was used. One after another of the members have departed, either by resignation or starvation, and now but two are left. One of these, the spiritual adviser of the society, Walter Lockwood Thales, is so nearly starved to death that he is confined to his bed from weakness; and the other, Mrs. Hinde, is so near the bound of life that the ladies living near her are forbidden to see her pale, wan face in the dying pangs of death by starvation.

A Two-pound Child.

Dr. S. L. Post reports in *Daniel's Texas Medical Journal* that he delivered a woman twenty-three years of age and the mother of three children, of a fœtus weighing only two pounds. There were no pulsations in the cord, which was cold and atrophied, and wholly detached from the placenta. After diligent work the child was made to breathe, and it is now as well as any infant. The woman menstruated regularly during her entire period of gestation, and during the last four weeks flooded so profusely that she was unable to attend to her domestic affairs.

An Elastic Mucilage.

The *Chemische Centralblatt* gives the following directions for an elastic mucilage:

Dissolve one part of salicylic acid in twenty parts of alcohol, add three parts of soft soap and three parts of glycerin. Shake thoroughly, and add the mixture to a mucilage prepared from ninety-three parts of gum Arabic and the requisite amount of water (about 180 parts).

This mucilage is said to keep well, and, when it dries, to remain elastic without tendency to cracking.

The Gropings of Medicine.

A physician was once conversing with a prince who spoke of medicine as a science of guess-work. "But, sire," he said, "let us suppose that an Egyptian darkness were suddenly to come over the land. Would you not rather trust to a blind man to guide you to Paris than to one who might see in the light; to one who had learned to grope his way in the darkness than to another who would stumble and go astray the moment his clear sight was dimmed?"

New Metric Abbreviations.

The International Committee of Metric Weights and Measures has adopted the following system of abbreviations. Italics are employed, with the exponents 2 and 3 to denote square and cubic measure: Metre=*m*, decimetre=*dm*, centimetre=*cm*, millimetre=*mm*, kilometre=*km*. Metre square=m^2, metre cube=m^3, and so for the rest. Litre=*l*, decilitre=*dl*, etc. Kilogram=*kg*, dekagram=*dkg*, gram=*g*, decigram=*dg*, centigram=*cg*, and milligram=*mg*.

Death of Another Patient of M. Pasteur.

A child, three years and a half old, is reported, in the *Semaine Médicale*, to have died lately from rabies at Teste. He was bitten by a mad dog on June 14th last. On the 16th he was brought to Paris, where, during ten days, he was submitted to Pasteur's treatment. After his return to Teste on June 28,

the child was seized on August 12 with the first symptoms of hydrophobia, to which he succumbed in a few days.

A Fortunate University.

Since 1879 the University of Sydney has received donations exceeding a million of dollars. One bequest, known as the Challis bequest, is expected to realize $1,000,000. The Macleay Natural History collection, another recent gift, is valued at $125,000, and a sum of $30,000 has been promised for the endowment of a curatorship in connection with it. For the purpose of founding a library a donation of $150,000 was made.

Artificial Quinine.

The *Lancet*, of August 28, intimates that Mr. Creswell Hewett has made a discovery by which quinine may be made by synthesis, from an article which may be got in abundance in any part of the world. It is thought that Mr. Hewett will put himself into communication with the British Government, which spends $300,000 annually in India alone in the cultivation of the cinchona tree.

The Coming Man.

A local chemist who lately advertised for an assistant was favored with, amongst other applications, one from an ingenuous youth, who, after detailing a few particulars as to where he had been and what he had done, begged to enclose his photograph, *and asked to see that of the advertiser in exchange.*

What a treat it would have been to see the face of that astounded pharmacist!

Roman Law and Medical Practice.

The Roman laws ordained, says Montesquieu, that physicians should be punished for neglect or unskilfulness, in treatment. If the physician was a person of any fortune or rank, he was condemned to deportation; but if he was of a low condition in society he was put to death, which was rather hard on the said physician of low condition.

Medical and Scientific Newspapers in Japan.

From recently published statistics of the Japanese press it appears there are seven medical papers, with a monthly circulation of 13,514; nine relating to sanitary matters, with a circulation of 8,195; and two on pharmacy. There are seven devoted to various branches of science.

Longevity of Intellectual Women.

Hannah More died at 88; Joanna Baillie, 80; Mary Russell Mitford, 70; Agnes Strickland, 74; Mrs. S. C. Hall, 80; Madam de Sevigne, 70; George Sand, 72; Mrs. Siddons, 76; Mary Somerville, 92; Caroline Herschel, 98; Fanny Kemble is living at 73, and Harriet Beecher Stowe at the same age.

Items.

—Chloral hydrate is used in Russia as a means of robbery.

—The Amsterdam quinine works are threatened with suspension.

—An English woman recently tried to commit suicide by swallowing soap liniment.

—During the past year $150,000 worth of licorice root was shipped from Smyrna to the United States.

—A Chinese edition of "Gray's Anatomy," prepared by Dr. John Dudgeon, who has resided in China for over twenty years, has lately been published.

—The vital statistics of Paris show that twenty-eight per cent. of all children born are illegitimate. Of still-born, thirty-five per cent. are illegitimate.

—Dr. M. Bertin, of Dijon, having ligated the common carotid for the cure of an angioma, found two years later that a new carotid artery had formed, slightly smaller than the original, but the pulsations were distinctly visible.

—Naphthalin leaves are prepared (*Pharm. Zeitung*) by applying a melted mixture of 25 parts of carbolic acid, 25 parts of ceresin, and 50 of naphthalin, to the surface of unsized paper placed upon a warm metallic surface.

—The attempt by the Chinese government, at Hong Kong, to cultivate cinnamomum cassia, is meeting with a serious drawback. The natives who use the leaves in medicine, persistently break off the leaves and branches, thus leaving the plants in almost leafless condition.

—According to the *Lancet*, Dr. Eustace Smith thinks highly of Monti's antiseptic treatment of whooping-cough, in which the child is caused to inhale, four times a day, a spray of carbolic acid (1 to 100), or of benzoate of sodium (1 to 20), and to take internally, every two hours, in milk, a suitable dose of tannate of quinine with benzoate of sodium and sugar. The average duration of the attack under this treatment is only three weeks.

Pallas Syringe." The most useful Instrument for Vaginal Medication and Irrigation.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Lecture.

VALVULAR DISEASE.*

BY PROF. WILLIAM H. DRAPER, M. D.,
Of New York.

Before having the history of the next case read, we will see what can be learned from the physical examination regarding his present condition without knowing the causes of it.

Inspection.—There is a visible pulsation of the ulnar, brachial, and carotid arteries, and the superficial veins of the arms and neck are distended and prominent, and the jugulars seem to pulsate. The neck is unusually large and thick, owing to a swelling of the thyroid gland.

You have sufficient evidence here from the character of the arterial pulsation and the obstruction to the venous current to justify you in the suspicion at least of some cardiac trouble. The thyroid gland is not unfrequently found to be enlarged in cases of heart disease, but more especially in functional disorders rather than inorganic disease of the heart.

Palpation.—The apex beat is much displaced, and it is felt in the fifth intercostal space and in the line of the axilla, that is, at a point about three inches to the left of the nipple. There is no cardiac thrill felt by the hand.

Percussion.—The area of cardiac dullness is increased principally to the left, showing a considerable hypertrophy of the left ventricle.

Auscultation.—There is no well marked and distinct murmur to be heard either at the apex or over the mitral valve, but at the base the second sound of the heart seems to be prolonged.

The pulse is full, large, and jerking under the finger and visible to the sight. It is that character of pulse which is sometimes called "Corrigan's pulse," from the man who first described its peculiarities, and sometimes the "locomotive pulse," or the "visible pulse," or the "water-hammer pulse." It is a very characteristic pulse, and it is almost invariably associated with one of the most important cardiac lesions, namely with aortic regurgitant disease.

Having finished the examination, we are now ready to hear the history of the patient read.

History.—Name, T. M. Age 37. An engineer. Born in the United States. Is married. Was admitted to the hospital December 6. Does not drink to excess regularly, but sometimes goes on sprees. Has never had any rheumatism or malaria.

Fifteen years ago he had a chancre on the penis, which was followed by a secondary eruption, and about a year afterwards he had an ulcer upon the skin, which finally healed. Has had no further specific trouble since. He was some time ago struck in the left eye with an iron wrench, which has left a scar in the shape of an opaque band across the pupil. One year ago, while in the West Indies, he was exposed to cold and wet, and he then caught cold. This was followed by pain and distress in the left epigastric region, and he became short of breath upon exertion. These symptoms have continued with more or less severity since. He has been on a spree most of the time since last April.

*Abstract from clinical lecture.

About a month ago his present difficulties began with indigestion and pain in the stomach and shortness of breath, and about a week ago he had a peculiar sensation, as if a fluid were running from his legs up into his chest. Since then he has suffered from slight headache and occasional attacks of vertigo. Has had no chill, no cough, and no vomiting. On admission his respirations were 36, pulse 88, temperature 100.4°.

One point of especial interest in this history is that the patient had constitutional syphilis fifteen years ago; for this disease is unquestionably one of the most important and frequent causes of arterial degeneration and of endo-cardial disorders. Another interesting point is the fact that he has gone on for a number of years with a cardiac disease which has not, until recently, interfered seriously with his work or his comfort. And when you consider that he has a hypertrophy of such extreme degree, and a cardiac lesion so extensive, as to produce obstruction to the circulation in the systemic veins, this long period of immunity seems to be an extraordinary circumstance. But, in fact, it is one which occurs frequently. The reason these people do not take any notice of their condition is because a compensation goes on for years, by an increase in the muscular walls of the heart and a dilatation of its cavities, and not until this compensation ceases to be made do they begin to suffer. So if you will go carefully into the history of these patients you will find that those difficulties which seem to them to be sudden developments are not such in reality.

In this man the fact of a prolongation of the second sound of the heart, most distinctly heard at the apex and over the mitral orifice, and less distinct at the aortic, points to a stenosis of the mitral orifice, and I think, also, an insufficiency of the aortic valves; and, perhaps, there is a distension of the aorta itself. For in cases of aortic insufficiency you will almost always get an accompanying dilatation of the aorta.

ANEURISM OF INNOMINATE ARTERY.*

BY MORRIS LONGSTRETH, M. D.,

Of Philadelphia.

The morbid specimens I have to show you to-day were removed from a man who came into the hospital to die. He was an old soldier, pensioned and housed at the Soldiers' Home. He came into the city to visit, and being overcome by his bad feelings sought relief here.

His chief and most distressing symptom was dyspnœa, which was so severe that he was unable to either walk or lie down. Examination of the chest revealed a double aortic murmur, but it was soft and mild, and of little import. There was no change in the area of cardiac dullness. The lungs were much congested, but showed no evidence of solidification. The temperature gave no sign of existing inflammation.

The post-mortem examination discovered this large aneurism, which in life could not be traced; it was situated post sternum, and was in fact practically cured, which accounts for the fact that neither pulsation nor blowing sound could be detected.

The patient could not talk, and had no friends, we were therefore unable to obtain any history of his past sufferings.

The aneurism is of the innominate artery, and about the size of a small fist. We thought the dyspnœa was due to direct pressure upon the trachea, but could not decide what caused the pressure.

Rest, aconite, and veratrum viride were prescribed. The patient could take no food, and his death was a question of but a short time.

For the dyspnœa and insufficient amount of urine secreted, we gave atropia, in quantities sufficient to produce effect. The pupils were well contracted, and we gave enough to dilate them—not fully, but to at least overcome the contraction. We were altogether guided by the effect on the pupil—at first giving $\frac{1}{60}$ of a grain hourly; then every two hours, and gradually less, till he was taking $\frac{1}{60}$ grain three times daily. The relief, though he was dying, was considerable.

I advise you to follow no rule, but give atropia when it is strongly indicated, as in the above case, for *its effects*. I have tested its efficacy, and can recommend it to you.

The autopsy shows that the aorta was very atheromatous and calcareous throughout, which caused the aneurism. After dilatation of the aorta, the aortic valve was insufficient. The heart is misplaced, and all the valves are stiffened and rough; the mitral valve thickened, but otherwise unchanged.

—Phosphorus-necrosis of the jaw is becoming quite common in England, in consequence of popular self-prescription of phosphorus as a brain renovator.

*Abstract of Clinical Lecture delivered at the Pennsylvania Hospital.

COMMUNICATIONS.

A NEW ACUTE ERUPTIVE DISEASE.

BY E. I. BEALL, M. D.,
Of Fort Worth, Texas.

In the MEDICAL AND SURGICAL REPORTER, September 4, 1886, there occurs an editorial review of a paper by Dr. Filatow, of Russia, upon "A New Acute Eruptive Disease." Will you be so kind as to allow me to state, through your columns, that in 1879 I contributed to the Texas State Medical Association a paper upon the very subject your comments refer to; and in that paper will be found somewhat similar views expressed, and in terms not very dissimilar to those which you present as being the purport of Dr. F.'s paper.

My paper was predicated upon a large number of cases of a disease presenting features alike of scarlatina and morbilli, which I saw in 1878 and 1879. It was published January 1, 1880, in the *Galveston Medical Journal*, at that time the organ of the Texas State Medical Association.

Furthermore, I forwarded a paper upon the same subject to Dr. Donklin, Sec'y Section of Children's Diseases International Medical Congress, London meeting, of which I heard nothing beyond a letter acknowledging its receipt.

As I have only a bound copy of the journal in which was published the transactions of the meeting of the Texas State Medical Association of 1879, you will please excuse "extracts" from that organ substantiating my prior claim towards asking a place for a *new* exanthem in our nosological table.

In answer to query three of the Chairman of Section of Climatology and Epidemics of the Texas State Medical Association, I had the honor to say:

"Two epidemics of especial note have occurred in this section within the past twelve months (1878–9)—'Rubeola' and 'Influenza.'

"The first-named disease began more than a year ago, making its appearance at first in the south part of the city (Fort Worth, Texas), whence it spread rapidly until nearly every child and many adults were among its victims. In a number of instances the infant of a few days as well as the old were included in the number. The disease lingered through a number of months, and even at the present time (March 20, 1879,) an occasional case is observed.

"I must be allowed to apologize for the diagnosis indicated above, as the profession were much divided in opinion in relation to the disease. One portion of the local profession were inclined to consider it scarlatina, another rubeola. There were numerous instances of the disease occurring in the person of subjects who had previously had measles, likewise scarlatina. Such instances were of so frequent occurrence as to place the fact without the category in which second occurrences of either disease are seen as the exception and not the rule with regard to those diseases, as well as the entire class of exanthemata. It exists as a fact, which an examination will corroborate, that scarcely any two writers agree as to the nature or in the description of rötheln. We are aware that measles and scarlatina were for a long period confounded together under the term of morbilli; and that even as late as the middle of the eighteenth century authors of reputed eminence contended for the identity of these diseases. At the present time, however, no one doubts a diversity in the two diseases: their differential character being so well marked as to indicate a wide variance, is now a recognized and indisputable assumption in medicine.

"Schonlein says that measles is a peculiar exanthematic form of catarrh, and that scarlatina should be placed among the erysipelatous diseases. When we shall consider the conclusions as advanced by Schonlein, when we bear in mind the observations of Kuttner, of Dresden, as to the eruption, symptomatology, etc., of rötheln, we may likely conclude with Hildebrand, Patterson, and Copland, that the disease is not one of a distinct or specific form, but that it presents features peculiar to both morbilli and scarlatina, and is in very truth a hybrid of the two, having an analogue in Surgeon Woodward's 'Typho-malarial hermaphrodite.' *When we shall thus conclude we will be confronted with the fact* that an attack of either morbilli or scarlatina is not protective against an attack of the disease in question, and *vice versa*. This conclusion I substantiated by repeated inquiries among intelligent patrons in the families of whom I observed the disease. Many of them were from the northern and western states, and their children unquestionably had passed through morbilli and scarlatina at some anterior period. I witnessed the disease in children whom I had treated for measles. These facts coupled with other peculiarities *led me to think that the disease is one of distinct and specific character*, showing, however, features

peculiar to both measles and scarlatina, yet sufficiently distinct to justify a place for it in nosology without confounding it with the disease with which it has been compared.

In the medical works at my disposal, I fail to elicit any account of rötheln that has exceeded in number of cases the epidemic upon which this article is based.

"From this fact I deduce an argument to further the position that the disease is distinct and specific: I refer to the mortality. Though many cases were seen, some of them grave in character, I believe it would be difficult indeed, yea, without precedent, to refer to any visitation of measles or scarlatina in which there occurred so few deaths.

* * * * *

"In many cases the eruption was the first evidence of the disease, though some were seen in which symptoms of illness preceded the eruption one to four days. The appearance of the eruption was innumerable fine, dark, punctated red points, upon a diffused extensive red or non-colored plane, the color gradually shading off. The eruption more distinct upon, and often confined to, the body and upper portion of limbs—rare on hands and face. Duration of eruption from one or two hours to seven or eight days.

The desquamation was fine and oftentimes not observed, except at flexions of legs and arms—sometimes upon the body.

* * * * * *

"A variation in symptomatology, and in appearance of the eruption, was observed; and I saw in same house, yea, in same bed, cases in which the variation in eruption, and somewhat in symptoms, existed.

"When catarrhal symptoms were most marked the eruption seemed modified, the large planes (disseminated) were more contracted, or divided into smaller patches, yet in color alike. These cases resembled measles.

"When the larger planes of redness existed, and throat symptoms were observed, scarlatina was well mimicked. In the scarlatinous variety the eruption was of longer duration; and the temperature was higher: 101°, 102°, and 103° F.

"When the morbillous variety was encountered the eruption was of shorter duration; temperature 99.5°, 100°, and 101° F.

"I saw the disease repeat itself the second time within two or three weeks.

"The disease herein considered may be a hybrid of scarlatina and measles, as has been suggested. I cannot think, however, that such is the case. If a specific disease and removed from the term rötheln, a blank surely exists in our nomenclature; and a place must be made for it, a name given, and recognized as an exanthem.

"The variation in eruption referred to above, sometimes a rubeola morbillosa, then a rubeola scarlatinosa, doses not separate in my mind the diseases, the one from the other. They are identically the same in essence; dependent upon the same genesis; may exist at the same time in the same bed; does not respect either previous scarlatina or measles; and though styled *rötheln*, does not answer a typical description, but to my mind, demands a recognition and a place with scarlatina, measles, varicella, etc. The variations in the eruption do not warrant the discrimination. Other diseases with one title show as great variations, and in the very class we would place the eruptive disease herein considered."

OVARIOTOMY, WITH THE HISTORY OF A CASE.*

BY ROBERT T. WILSON, M. D.,

Of Baltimore,

Gynecologist to the Union Protestant Infirmary; Assistant Surgeon to the Hospital for the Women of Maryland.

[Multilocular ovarian cyst; removed by incision through the linea alba, of three inches; pedicle ligated with silk, returned to the abdominal cavity; drainage; recovery.]

The patient whose history forms the subject of this report is the mother of three children, two girls and a boy, the youngest child, a girl, being now two years old. She has been married eleven years, and is the second wife of her husband. She has just reached her thirty-fifth birthday. At the age of thirteen she first menstruated, and it has always appeared every four weeks ever since, except when she became pregnant. When her last child was born she did not suffer with labor pains like she had with the other children. This time her feelings were severe cramps in the lower part of the abdomen, and no pains in the back. She was only two hours in labor, it being also the easiest of any, considering it upon the whole. While she carried this child she always had a soreness in the left groin. Bowels were moved every day without medicine. After the labor the abdomen did not go down as it did after the birth of the other children; so that she could not tell me when the abdominal enlargement began. In July, 1884, she had had feelings as if her womb had fallen out of place, so she consulted a physician

*Admission Thesis to the Baltimore Academy of Medicine. Read June 1, 1886.

near her home. He placed a cup-shaped pessary in the vagina, telling her it would keep her womb up. In November, 1885, she consulted my father, Dr. H. P. C. Wilson, and upon making a digital examination, he found that she had a retroverted uterus, and that the cup pessary was buried in the vaginal tissue, and had made a sulcus, deep enough around the cervix uteri to bury the finger in it. On removal of the pessary there was profuse hemorrhage from the sulcus; the effect of the pessary had been to raise the cervix high, and throw the fundus uteri more firmly back into the hollow of the sacrum, where it was firmly fixed in surrounding lymph. Upon further examination he diagnosed cystic tumor of the left ovary. She remained awhile for reparation of the damages done by the pessary, then returned to her home to pass her menstrual period, which was approaching. She returned to the city December 12, and entered the Union Protestant Infirmary under my care. She then told me, in addition to the above history, that she did not suffer with her last menstrual period, or with it prior to that period. Upon examination per vaginam I found the uterus retroverted, and kept down by adhesions. Upon palpation and percussion I diagnosed a multilocular ovarian cyst of the left ovary. The patient being prepared, on the 15th of the same month I operated, the anæsthetist being Nathan R. Gorter, M. D. An incision of two inches through the linea alba was made; as soon as the peritoneum was cut through and abdominal cavity reached, out poured a great quantity of serous fluid, blood being mixed with it. The tumor was found to be strongly attached to the abdominal walls, to the left of the incision. The incision was enlarged and the adhesions broken up. Sir Spencer Wells' trocar was plunged into the tumor, and at once was discharged fluid of a chocolate color. A second cyst, upon being tapped, discharged a clear viscid fluid. The hand was now introduced into the tumor and several smaller cysts broken up; grumous fluid containing flocculent lymph now flowed from the tumor. Upon the tumor collapsing, the omentum was seen to be closely adherent in several places to the superio-posterior part of the tumor. Some difficulty was experienced in separating these adhesions, which, on being done, bled, but were immediately clamped and tied with Chinese silk. The intestines were also adherent to the posterior part of the tumor; with care they were peeled from the tumor. The tumor was now raised out of the abdomen. The pedicle was found to be one inch and three-quarters in width and of medium length. I now transfixed it with my temporary clamp, tied it with a double ligature of Chinese twist silk, cut off and returned into the abdomen. After the peritoneal cavity had been carefully sponged, it was found that some oozing of serum mixed with blood continued. As ligatures had been left upon the omentum, and this oozing continued in the cavity, it was deemed advisable to provide for drainage; so I inserted a soft rubber drainage-tube with holes cut into it by myself, where I thought they were needed, the tube reaching down into Douglas' cul de sac, and out through the lower angle of the incision. The abdominal wound was closed with seven silver-wire sutures, and dressed antiseptically. Time of operation, forty-five minutes. The patient was now placed in bed, with warm applications to her feet. During the operation, her body was kept warm with hot bottles and blankets. She reacted very well. At 9 o'clock p. m., I examined the dressing, and fully ℥ij. of bloody serum had been discharged, and it was still running from the tube. I withdrew from the tube, with a hard-rubber syringe having a long nozzle, the fluid, and washed out the cavity with boiled water blood-heat, made further antiseptic with carbolic acid (1 to 40); fresh dressings applied. She passed her urine without any trouble in the bed-pan. On the morning of the second day the dressings were removed, and fully ℥j. of bloody serum had run out and the tube was only partly filled. The cavity was treated in same manner as the night before; wound looked well. General condition of the patient good. Night of the second day dressing removed, about ℥j. of fluid discharged, tube being half full; same management continued. Morning of the third day, dressings removed; very slight discharge had occurred since last night; same treatment observed. Night of third day, discharge stopped, tube removed. Wound looked well; dressed it antiseptically. General state of patient good. Morning of fourth day, wound looked well, no discharge from it, dressed it as usual. She so continued, and made an uninterrupted recovery.

The greatest point of interest in this case was the drainage-tube. From the amount of bloody oozing from the points where the tumor was attached, which even the most thorough sponging and afterwards touching with liq. ferri. subsulph. did not stop, and judging from cases I have seen in my father's and my own hands which also recovered, I am confident that this patient's life was saved by the drainage tube.

Before taking my seat, I desire to show a photograph which I made myself, which shows the appearance of the abdomen prior to operating.

ORAL DISEASE AND CASEOUS PHTHISIS.

BY JOHN S. SMITH, D. D. S.,

Of Lancaster, Pa.

Mr. S., aged about 20 years, tall of stature, blue eyes, light complexion, light hair. Having graduated at the Mount Joy Soldier's Orphans' School at the age of 16 years, and for several years subsequently a member of the Reynolds Rifles, of Lancaster, Pa., Co. C. Eighth Regiment National Guard of Pennsylvania, visited me in November, 1885, for consultation in regard to an ulcer on the right cheek which had bothered him for over four months. His general health was poor, and besides the abscess, which was discharging on the face, he was bothered with a cough, principally at night after lying down; he also complained of pain over the right side of the chest. The man had lost in body weight, and presented an anæmic appearance. He related to me the following history of his case:

About one year before, in 1884, he suffered from chest trouble to some extent, but during the summer following he went to the country, and came back feeling, as he said, like himself again, having gained considerably in weight. He resumed work again, as an employee in a cork factory in this city. On the occasion of the fall (1885) encampment of the National Guard at Mt. Gretna, he reported with his company for inspection, and while there he had a severe and painful swelling on his right cheek. He reported to the surgeon in charge, and was told to open the gum-boil, which would soon appear on the gum. He suffered excruciating pain for some time, and as a last resort applied a salve made of soap and sugar to the cheek externally, which opened the abscess on the outside. The salve had the tendency to break up the integument of the cheek, and the parts became very much inflamed. Upon his arrival home he placed himself under the care of a physician, who attended him for several months, with but little if any beneficial result.

I made a careful examination of the case, first removing a strip of adhesive plaster from the ulcer, which revealed an unsightly sore, about ¾ by ½ inch above the border of the jaw and a little back and over the facial artery on the cheek. The ulcer was sunken, with loose skin hanging over the raw surface, which was much inflamed. In the center a large sinus was discharging a thin watery fluid. Upon looking into the oral cavity, it was observed that the teeth of the lower jaw were large and crowded for room. The teeth were all in place, and apparently free from caries, with the exception of several which were slightly decayed, but not to affect their pulps. The wisdom teeth on both sides of the jaw were through the gums, but crowded well back on the ramus of the jaw. While the right side was abscessed externally, the left side around the wisdom tooth was also discharging pus within the cavity of the mouth. This being the general history of the case, the diagnosis was plain.

Diagnosis.—To look at the oral disease from the dento-surgical standpoint, would indicate death of one or more pulps of the teeth. The teeth, by a careful examination under the usual tests, showed living pulps; we must therefore exclude pulpitis, and devitalized pulp. It has been noticed the teeth are crowded for room, and in the eruption of the third molars, the undue pressure exerted in their eruption caused inflammation of the periodental membrane, and resulting in suppuration and abscess, and necrosis of a portion of the external plate of the alveolar process.

The patient being strumous, would still add fuel to the flame excited by the crowded condition of the teeth, and pulmonary trouble had sapped the system to some extent of its vitality, which would greatly interfere with nature to throw off the disease without the assistance of the proper remedies. As it was, the ulcerated face and jaw was slow to heal, even after the operation.

Treatment.—The removal of the wisdom tooth, which was not an easy matter to accomplish. The wisdom tooth on the left side was discharging pus around the socket, and as the bone was not diseased, nothing more was needed to effect a cure on that side. On the right side other treatment was indicated. Stimulating injections could now be forced through the fistula from the alveoli. Tincture of iodine and diluted carbolic acid were chiefly relied on, used alternately—every day for one week the iodine being packed (full strength) on cotton wool in the alveoli, until the line of demarcation was established. The dead bone was subsequently removed, and all spicula trimmed smooth by the aid of a rose-shaped bur and the dental engine. This completed the treatment within the oral cavity. Attention was now

directed to the large ulcerated surface on the cheek, which was still raw and devoid of cuticle. The discharge from the sinus having ceased, the parts soon showed signs of healthy granulation, and with no other dressing than phenol sodique one-half strength during the first week, and subsequently diluted to one-twelfth its original strength, until scar tissue was completed, which was in about eight weeks after the abscess ceased voiding. The cheek at this time was perfectly healed, having somewhat of a sunken or depressed appearance, but not nearly so much as was expected from the nature and extent of the break of continuity of the soft parts.

As the weather became inclement and changeable during the following January and February, the lung disease became more severe, the patient was unable to leave his room, except at short intervals, when the weather permitted, he ventured out for exercise. The walking would soon tire him, and he was glad to get back to his room. As the disease progressed, the symptoms became more aggravated. Night sweats, and cough, fever, pains in the chest, and the usual characteristic expectoration, emaciation, but no diarrhœa. The appetite did not fail him until within a short time before the middle of February.

When treating the oral disease, I put the patient on a course of iron treatment, and subsequently the syrup of the hypophosphites was administered, which treatment apparently was beneficial. When the night-sweats came on the proper remedies were prescribed internally, as well as externally by sponging the skin, which afforded relief.

In February, about the 12th, I suspended my visits, as the oral disease was cured, and he was having no more trouble from that source. I advised the family to call in a physician to take charge of the case, which they did. The patient, however, began to sink, and died in March, about four weeks afterwards, of caseous phthisis.

VALUE OF POMEGRANATE BARK AS A TÆNIAFUGE.

BY L. S. BLACKWELL, M. D.,
Of Perth Amboy, N. J.

The omission of any reference to the pomegranate by some writers on therapeutics, and the comparatively scanty literature on the subject generally, is calculated to impair confidence in its merits, and stamp it as a remedy of inferior importance.

With no desire to rank it as a specific, it certainly possesses in its properties and physiological effects advantages over those drugs which stand preëminent in the treatment of tape-worm.

As it is less repulsive to the palate and decidedly less nauseant than male fern, it claims the attention of physicians, and merits a trial in the cases of tænia which present themselves for treatment.

The following case is somewhat unique, by the absence of any subjective evidence of the presence of a parasite of this kind in the intestinal canal—positive proof being furnished by the expulsion of segments of the worm in the alvine dejections:

E. H—— presented himself for the treatment of tape-worm, May 16, 1883. I prescribed for him two fluid drachms of the oleoresin of male fern, made into an emulsion by the addition of a similar quantity of tincture of soap bark. This had the effect of causing the removal of the larger part of the worm, but the preparation was so repulsive that the patient was unwilling to repeat the prescription.

Some time after this he applied to another physician, who also undoubtedly prescribed the same preparation, and with a like result upon the palate and the parasite. Recognizing the objectionable features of the drug in this instance, and its inefficiency, so far as the expulsion of an important part of the worm was concerned, and recalling to mind the success which followed the administration of the pomegranate to a lady living in Wilmington, Del., I decided to give it in this case, and directed a decoction to be made from two ounces of the bark, and administered in wineglassful doses every two hours, the patient fasting during its administration. The only preliminary treatment was fifteen grains of calomel and four of gamboge given on retiring the previous evening. A slight nausea occurred at the commencement of the treatment, but it soon subsided, and the drug was taken with slight inconvenience to the patient, but had a decidedly disturbing influence upon the worm, which was expelled in three sections, measuring in its entirety twenty-seven feet, the head, attached to the filiform neck, presenting evidence of vitality.

The head of this parasite under a small microscope presented a striking similarity to the description and illustration of the *tænia medio-canellata*, as furnished by Aitken in his comprehensive treatise on the "Science and Practice of Medicine."

—A sign painter erroneously made a druggist's sign read: "Physicians' prescriptions carefully confounded."

Medical Societies.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, May 28, 1886. The Vice-President, Dr. Daniel Longacre, in the chair.

Dr. Longacre read a paper entitled

Retarded Dilatation of the Os Uteri a Symptom of Faulty Mechanism. Illustrated by Presentations of Brow and Face. Occipito-Posterior, Transverse and Breech Presentations.

The paper will be published in full at a future date.

Dr. Clara Marshall reported a case of

Mammary Abscess, During Pregnancy, in a Primipara.

Lizzie H——, German, aged twenty-seven, single, domestic, pregnant, with a family history of phthisis (her father and mother having died of that disease), was admitted to the surgical department of the Philadelphia Hospital, January 21, 1884. When admitted, she was suffering from an affection of the right breast. Examination of the lungs revealed the presence of incipient phthisis. As the patient did not come under my care until confinement, Dr. Joseph Hoffman, interne, kindly furnished me with some brief notes of the case, from which I now quote. The right breast was greatly enlarged, and its appearance so far suggested malignant disease, that the idea of incision was contemplated. With this in view, a consultation was held, resulting in the abandonment of the cancerous view, and mammitis was diagnosticated; the correctness of which diagnosis the subsequent history justified. Poultices were applied, and in a few days pointing occurred and the abscess was opened. Soon two or three other points of suppuration were observed, and the pus was evacuated by incision. In the meantime the breast was supported in a mammary sling.

March 1. The treatment of the case by means of compressed sponge (after the method of Foster) was instituted. This treatment, for the first week, seemed to act favorably, but at the end of that time so much pain was experienced that the dressing was, of necessity, abandoned, and poultices were reapplied. During the time of the application of the poultices, and subsequently, large quantities of pus were evacuated by free incisions. Adhesive strips were now applied with the effect of relieving pain, by the support which they gave, and at the same time the pressure aided in the evacuation of the pus. Within a week they were, of necessity, removed, several points of inflammation having appeared beneath them, with the production of much pain. The pain was relieved by several incisions, resulting in the evacuation of nearly a pint of pus. Throughout the progress of the case, opiates had to be used to a considerable extent; the medication also included quinia, iron, whisky, and, later, cod liver oil. No temperature chart was kept, but a rise above the normal was noted at intervals, coinciding, for the most part, with the accumulation of pus, and abating as soon as this was evacuated. The highest temperature noted was 104° F. The swelling of the breast, which began about two weeks before her admission to the hospital, the patient attributed to having taken cold, though there was no history of a chill.

The patient was admitted to the obstetrical department April 23, 1884, and upon the same date, after a normal labor, she was delivered of a poorly-nourished male child, weighing five pounds and twelve ounces. This infant was never healthy, and died May 5 (twelve days after birth).

From May 1 (seventh day after confinement) the treatment consisted in extending the various openings by free incisions and by packing the sinuses with lint soaked in carbolized oil. Subsequently a drainage-tube was inserted into the one deep central sinus and carried down to its deepest part. Through this tube a solution of corrosive sublimate (1 to 1000) was injected daily, the injection being continued until the solution returned free from pus. During the intervals the mouth of the tube was protected by a layer of lint saturated with the corrosive sublimate solution. The other sinuses were also washed out and packed with lint wet with carbolized oil. The breast was firmly dressed, daily, with adhesive plaster. The pus became healthy in character, and diminished in quantity, and the sinuses healed, with the exception of the central one. The patient's condition improved, and she was able to leave her bed and walk about the hospital grounds.

July 1. The central sinus is yet unclosed.

July 14. The breast is somewhat indurated, but every sinus is healed.

The infrequency of mammary abscess in pregnancy, as compared with its occurrence in the puerperal state, is illustrated by the statistics of Mr. T. W. Gunn, surgeon to the Middlesex Hospital. Of Mr. Gunn's 72 cases 58 occurred during lactation, 7 during pregnancy, and 7 in women who were neither pregnant nor in lactation. The points

of suppuration in the case I have reported were so numerous that it would be of great interest had there been obtained an accurate estimate of their number. Velpeau records a case which he thus describes: "The breast looks liks a large sponge impregnated with pus, or like the nozzle of a watering-pot, there being fifty apertures for the escape of pus."

Apropos of the suggestion of malignancy, early in the case, I may again quote Velpeau, who says: "Such a mistake was committed a few years ago in one of the great hospitals in Paris by one of the most eminent and experienced practitioners." Sir Astley Cooper reports a similar case, and says: "I could point to other cases. This mistake is more liable to occur when the abscess is *chronic* in character."

In the discussion which followed the report of Dr. Marshall's case, Dr. Daniel Longacre said that he was in the habit of using Billroth's method in the treatment of mammary abscess: "Open every sinus freely, clean out the necrosed tissue, wash out the sinuses, and then apply an antiseptic dressing."

Dr. Susan P. Stackhouse reported the case of a mammary abscess in an unmarried, non-pregnant woman: "C. M., æt. 20 years. Right mammary gland twice the size of the left. Very painful, fluctuation easily detected. The patient was very much excited, and when told that it would be necessary to lance the breast, made considerable resistance. Finally she allowed the abscess to be opened, and a free flow of pus followed, after which there was great relief. The subsequent history of the case was without interest. The abscess had been developing for four weeks, and the patient's friends told her that it must be a cancer. There was no pain in the part until the fourth week, the swelling being the only symptom. The patient was thoroughly examined, but no symptoms of pregnancy could be detected."

Dr. Calista V. Luther mentioned a case of threatened mammary abscess in a male, which was aborted by means of the use of bandages and cold compresses.

Dr. Mary Willits related a case which had come under her observation. The patient would not permit the lancet to be used. As a consequence the abscess had opened spontaneously in *four* separate places; from each of these there was a free discharge of pus and milk for some days. At present there is no discharge of pus, but the milk is flowing freely all of the time, the patient's clothing being kept saturated. The breast was bandaged with strips of adhesive plaster, having in view the bringing of the edges of the sinus in contact, and hoping to hasten their union in this way; but in a few hours these strips were entirely loosened, owing to the flow of milk. Dr. Willits asked if the members of the Society could suggest any means by which to hasten the healing of the parts. It is not desirable to *arrest the secretion* of milk, as the patient has an infant three months old.

Dr. Mary E. Allen suggested compression of the gland by means of the roller bandage. She spoke of a case of her own where firm compression was made by means of the bandage, and no milk came into the gland.

Dr. Daniel Longacre referred to Dr. Philander Harris's plan of "The Treatment of Mastitis by Bandaging and Rest," an account of which appeared in the *American Journal of Obstetrics* in the January and February numbers for 1885.

Dr. Clara Marshall would suggest the use of compressed sponge in the case mentioned by Dr. Willits. By applying the sponge *dry*, securing it firmly by means of a roller bandage, and then moistening it, the swelling of the sponge caused by the moisture causes great pressure on the gland, which will bring the edges of the sinuses together and thus hasten union. In this case the flow of milk would be apt to produce enough moisture. In a chronic abscess where there is no pain compressed sponge acts very nicely.

MARY WILLITS, M. D.,
Reporting Secretary.

CLINICAL SOCIETY OF MARYLAND.

Endermic Medication. (*See page* 386.)

DISCUSSION.

Dr. John Lynch corroborates Dr. Waters' statement respecting the success of blisters in idiopathic erysipelas. The blister should be of sufficient size to cover entirely the inflamed area.

Dr. H. Clinton McSherry has had most happy results from the application of blisters over the thorax in early stages of pleurisy and pneumonia. In acute laryngitis without œdema blisters give great relief, and may in some cases abort an attack.

Dr. Randolph Winslow asked Dr. Waters whether he had used blisters in the deeper forms of erysipelas, or only in the cutaneous variety.

Dr. Waters replied, he had employed vesication only in the simple cutaneous erysipelas.

Dr. Winslow said he thought this a very important point: Erysipelas is usually classified as cutaneous, phlegmonous, and cellular, but there is probably a difference in the pathology of the superficial and deep forms, and whilst vesication might be of advantage in the superficial varieties, other methods of treatment would almost certainly yield better results in the deeper. He also called attention to the fact that the superficial variety rarely terminates fatally, but after a certain length of time begins to subside, and in 24 or 48 hours marked improvement might be noticed, so he did not know how much to attribute to the remedy in these cases. Many cases of erysipelas are accompanied with vesication, as in a case recently under Dr. Winslow's treatment, where the hand and arm was as freely blistered as if cantharides had been applied to the surface, with free secretion of serum, and he had not found that such did better than those in which it did not occur.

Dr. Lynch states that a blister placed upon the sound skin will prevent the advance of erysipelas beyond that point, but it it is difficult to understand the *modus operandi* in such cases; certainly it is not on account of its depleting effect upon the healthy skin. We must accept statements in regard to the treatment of cutaneous erysipelas with great caution, but if it is a fact that blistering will arrest its progress, we are to be congratulated upon having heard Dr. Waters' paper.

Dr. W. H. Norris has never departed from the practice of bleeding and blistering; thinks physicians of the present day make a mistake by dispensing with these valuable agents.

Dr. E. M. Reed thinks general condition of patient should be considered before blistering in erysipelas.

Dr. John Lynch has tried nearly all of the treatments recommended in erysipelas, and gets about the same result. Thinks the tendency in the disease is to run a regular course, which is but little affected by any treatment. Thinks fatal cases are the result of hyperpyrexia.

Dr. A. C. Pole agrees with Dr. Lynch. He recently prescribed for a patient with erysipelas, and did not discover until the patient was convalescing that he had made a mistake in the dose. The result was as good as if the prescription had been as he intended it.

Dr. I. E. Atkinson expressed skepticism upon the abortive treatment of erysipelas. Don't think blistering or marking by nitrate of silver has any effect at all. Don't think that fatal cases are the result of hyperpyrexia. When an erysipelas of the upper part of the body or head proves fatal he thinks it due to an extension of the process to the meninges. In his opinion the disease is hardly sufficiently dangerous, nor are the chances of doing good by blistering enough, to justify us in risking the disfiguring cicatrix that may follow a blister. Cannot possibly conceive the advantage to be derived from blistering in migratory erysipelas. Many cases, as Dr. Winslow has just said, blister spontaneously without any apparent benefit upon the course of the disease.

Dr. W. D. Booker agrees with Dr. Atkinson as to the cause of death in these cases being often a secondary meningitis. He related a case of fatal meningitis resulting from a facial erysipelas complicating perforation of the tympanic membrane.

Dr. Wm. A. Moale made some remarks upon, and showed photographs of a case, upon which he had performed *double supra-condyloid osteotomy.*

He did McKewin's operation first on one leg, and after an interval of about eighteen months on the other one.

The operation was a success in every respect, the patient being able to walk perfectly. He exhibited the instruments used in doing the operation. His results on several of these cases have been so uniformly favorable that he would advise the operation in all of these conditions.

In answer to Dr. Platt, as to how long after the last operation was it before the patient could walk without assistance, he said she walked perfectly after about four months.

Dr. W. B. Platt thinks Dr. Moale's results remarkable, as in most of these cases, the internal ligaments of the knee-joint are so relaxed that they walk with difficulty.

Dr. J. Edwin Michael thinks this the first case of double supra-condyloid osteotomy reported in this city.

He has done the operation on one leg. He adapted MacCormack's operation, and observed antiseptic precautions. So far as straightening the leg goes, the operation was a success, but can not report on the progress of the case, as the patient left the hospital and did not return. He thinks the results justify the operation.

Dr. John N. Mackenzie related a

Case of Lymphoid Growth in the Pyriform Sinus.

The tumor arose from the anterior right hand side of the pyriform sinus. It grew

until it almost entirely obliterated the opening to the larynx. It was movable. To remove the growth it became necessary to cause retching when it was partially extruded. It was then grasped with the forceps, which were held by an assistant, while the wire of an ecraseur was passed around its pedicle, and in this way severed it from its point of attachment. Though the growth itself was very vascular, but little hemorrhage accompanied the operation.

There has been no return of the growth. Dr. Mackenzie has not been able to find any report of a growth arising from this locality.

Dr. W. T. Councilman, to whom the tumor was referred for microscopic examination, reported it to be a papilloma. In size, it was about that of a testicle of a man. Pharyngeal growths usually arise from the posterior wall, rarely from the anterior. Cancer has been found in the pyriform sinus.

Urinary Incontinence of Children Treated by Anodynes per Rectum.

Dr. Edward T. Williams thus writes in the *Boston M. and S. Jour:*

It is safe to say that the modes of treatment usually recommended for this distressing infirmity are frequently ineffective and disappointing. A failure of my own some years ago with a child nearly related and especially dear to me, led me to cast about for some improved method. For the past year or two I have been trying, with complete success thus far, the use of anodynes by the rectum, in the form of injections and suppositories of morphine, belladonna, or atropine. I have now cured about six cases by this means, besides temporarily relieving many more who have passed out of sight during treatment, so that I cannot positively state the final results. I have no doubt, though, that a portion of these have been cured. Some of them were patients of the Sea Shore Home, where the length of stay averages less than a fortnight—too short a time to effect a permanent cure in any case. One of my cases, which I will describe presently in detail, had been a constant sufferer for ten years. The treatment occupied a year, off and on. She is now entirely well.

I find that morphine alone relieves for the time being, but does not cure. Belladonna and atropine are curative, when continued long enough, though I find them to be better borne in combination with a little morphine, which counteracts some of their bad effects, and enables them to be given more continuously. Furthermore, the requisite dose of belladonna is smaller when combined with morphine. When these medicines produce headache or undue nervous excitability, I use the bromides as a corrective, or suspend their administration for a time. I have found no case where they could not be borne when properly given.

As to the mode of administration, a fifteen grain suppository of cocoa butter is most easily handled, and that which I prefer. They should contain a proper amount of extract of belladonna and morphine. For a child five years old, say, one-eighth of a grain of belladonna extract, and one-sixteenth grain of morphine; but the doses must be carefully adapted to the particular case in hand, beginning with a small dose, with a smaller relative proportion of belladonna, and increasing the latter and diminishing the morphine as toleration becomes established.

If an enema or clyster be preferred, it should consist of about a drachm of lukewarm water, with a few drops of atropia and morphine solution added, and administered with the small hard-rubber syringe (No. 2) especially designed for the purpose. The old-fashioned clyster of starch-water and laudanum is absurdly out of date. I have used nothing for years but morphine and warm water, mixed as for a subcutaneous injection, only that the water should be tepid, and not exceeding a drachm in amount. I hardly dare claim to be the originator of this self-suggestive plan, though I certainly never heard of its being done by others before I adopted it out of my own fancy years ago, since which time I have freely mentioned it in conversation and before various societies. It is certainly the simplest form of anodyne clyster.

At the Sea Shore Home, where we do things by wholesale, I have two solutions of morphine and atropia ready made. The first

consists of one-sixth grain of morphine and twenty minims of water. The dose by drops therefrom is the same as that of laudanum, which makes it especially convenient for the nurses. The other is one-sixtieth grain of atropine to twenty minims of water. Reckoning one-sixtieth of a grain as an average commencing dose for an adult, the dose for a child may be graduated by drops precisely as with laudanum. For a child five years old, then, as an enema, you might give for a commencing dose from three to five drops of each solution, mixed with a teaspoonful of warm water. These doses may be differently combined or altered in any way to suit a particular case.

I mention these points because it is convenient to have both in private and hospital practice certain methods of routine, not only to save thought and labor, but to lessen the chances of mistake.

I will conclude by recounting a single case as an illustration of this mode of treatment. A bright and charmingly pretty girl of fourteen came under my care for this disease July 9, 1883. Had been subject to it for years, in fact nearly all her life. Was of a peculiarly sensitive, nervous temperament, and subject to convulsions in infancy and early childhood, for which I had myself attended her. Was just beginning to menstruate. The urinary trouble had become a great source of mortification to her, and her shyness about it was so great that she could not be brought to talk with me on the subject, so that all communication had to pass through the mother, a thing I should hardly have put up with if it had not been one of my particular families. This being my first case (of rectal treatment) I began with morphine alone, one-sixth of a grain nightly, in suppository. Failing to produce full relief I doubled the strength, making one-third of a grain, when she went nearly a month without once wetting the bed. On stopping the suppository the trouble quickly returned. Recommenced the one-third grain suppository on September 14th, with full relief of the incontinence as before, but the patient, who was attending school all the time, began to get "fidgety" and nervous from the effects of the morphine, so that I was compelled to give small doses of bromide of potassium daily. This relieved the nervous symptoms entirely. I then began to taper off on the morphine, giving a suppository every second or third night instead of every night, or occasionally halving the suppository. On this treatment she began to wet more frequently, and I became satisfied that morphine alone would not cure her. October 29th I prescribed a suppository containing one-sixth grain of morphine and one-fourth grain extract of belladonna. On December 10th I made it one-eighth grain morphine and one-half grain extract of belladonna. Both these answered perfectly, and in six weeks she was practically cured. In the succeeding six months she did not wet more than six times, but each time was carefully followed by the use of the belladonna suppository for one week to prevent a relapse. For two years now, since the summer of 1884, she has been perfectly well and improved greatly in general health.

I might report other cases far more rapidly cured. I select the above on account of its long standing, and, since I was obliged to proceed somewhat tentatively, as showing very well the comparative action of morphine and belladonna. The latter I have never given without some morphine, believing they act better in combination, as they do when given by the mouth.

From my present experience I regard the rectal treatment as superior to all others in this disease.

The Differential Diagnosis of Scrotal Tumors.

Professor D. A. K. Steele read a paper on this subject before the Chicago Medical Society.

For diagnostic or clinical purposes tumors of the scrotum may be divided into two general classes, viz.: reducible and irreducible —reducible tumors including all herniæ (except strangulated), varicocele, and congenital hydroceles. Irreducible tumors of the scrotum would include all tumors connected with the testicle, all hydroceles (except congenital), and strangulated hernia. Tumors of the tegumentary surface of the scrotum, such as inflammatory œdema, elephantiasis, and epithelioma, are usually so characteristic in their history as to offer no special impediments to a correct diagnosis.

Scrotal hernia may be mistaken for:

1. Hydrocele of tunica vaginalis, cord, or encysted hydrocele.
2. Sarcocele of the testicle, simple, tuberculous, cystic or malignant.
3. Varicocele.
4. Hæmatocele.
5. Bubo.
6. Undescended testis.

In scrotal hernia, as a rule, the tumor is soft and doughy to the touch, light weight, smooth and regular, painless unless inflamed

or strangulated, of sudden advent from above downwards, resonant on percussion, fills the inguinal canal, has cough-impulse, gurgles, is of normal color, opaque, may exist on either side; the spermatic cord is concealed, does not fluctuate; aspiration is negative, bowels may be embarrassed. It can be reduced unless the hernia is strangulated or incarcerated.

1. (a) In hydrocele of the testicle the tumor is ovoid or pyriform, develops slowly from below upward, is firm, tense, and elastic, fluctuates, is translucent, dull on percussion; is irreducible; spermatic cord is neither concealed nor displaced; the inguinal canal is empty; bowels unaffected; aspiration reveals fluid.

(b) In hydrocele of the cord the difference is that the tumor is circumscribed, encysted, and sometimes reducible; situated usually near the epididymis, but returns after reduction irrespective of position.

(c) In congenital hydrocele the fluid disappears completely within the peritoneal cavity by compression of the tumor a short time.

2. (a) In sarcocele of the testicle the tumor is usually hard and resistant, heavy, often nodular and irregular; painful; grows slowly; dull or flat on percussion. The inguinal canal is empty; no impulse on coughing; bowels unaffected; irreducible; no auscultatory sounds. Simple sarcocele is chronic orchitis. Both the epididymis and body of the gland are affected. The cord is usually thickened. Abscess of the organ may occur. It is caused usually by an injury followed by inflammatory deposits.

(b) Tubercular sarcocele is met with most frequently in early manhood, and may occur in any constitution; in the strong and robust as well as the weak and cachectic; and although often associated with tuberculariza-tion of other organs, it is common enough to find the tuberculous nidus in the epididymis, not as a sequence of gonorrhœal inflammation or some slight injury followed by inflammatory infiltration—as was formerly believed—but as a coincident.* The progress is slow and insidious. The gland at first moderately enlarges with little or no pain, the hypertrophy being especially marked in the globus major. Presently the outline of the tumor becomes craggy and nodulated, and circles around the testicle from behind forward in the form of a crescent. After several months this adventitious tissue exceeds in size the testicle proper, and then it begins to soften at points, and one or more abscesses burst and discharge a thin shreddy pus. The vas deferens is greatly enlarged.

(c) In syphilitic sarcocele or gummata the history of the patient guides us in the diagnosis. Also we find that the body of the gland is usually the seat of the infiltration, which takes place in the connective tissue between the tubuli seminiferi, the epididymis undergoing little if any enlargement, the cord and vas deferens are unaffected, there is little or no tenderness, and the peculiar sensation elicited by squeezing a healthy testicle is absent. The tunica albuginea is very greatly thickened. Hydrocele is a frequent complication, and tapping is often required to establish a diagnosis.

Cystic tumors of the testis closely resemble hydrocele, and differ chiefly in being opaque instead of translucent. Aspiration should be practiced before pronouncing positively upon their character.

Cancer of the testicle primarily invades the body of the gland, and almost invariably assumes the encephaloid form. Most observers doubt the existence of other varieties of malignant disease in this organ. The development of the disease is rapid. The patient has a sensation of weight, pain, and dragging in the testis, the scrotum becomes distended, reddish, or purplish, and the superficial veins are seen to be enlarged. The skin adheres to the gland, ulceration occurs, fungus protrudes, the inguinal glands are secondarily involved, and the patient by this time presents the characteristic cancerous cachexy.

3. In varicocele the tumor is knotty and irregular, like a bag of worms; bluish in color; most frequent upon the left side; increases in size upon the application of heat; develops gradually; is dull on percussion; fluctuation doubtful; spermatic cord not affected; inguinal canal not involved. No cough-impulse. It reduces spontaneously by any position that favors increased venous return, but returns immediately when the patient stands up, notwithstanding pressure at the ring. There is weight and dragging in the scrotum.

4. In hæmatocele the advent is sudden, usually traumatic in origin; grows from below up if spontaneous; fluctuates until coagulation occurs; is at first soft, and hard after coagula form. It is pyriform in shape; ecchymotic; irreducible; heavy; dull on percussion. The spermatic cord is unaffected,

*The bacilli tuberculosis which were formerly probably disporting in the blood in a state of innocuous desuetude, now finding a fertile soil in the increased vascularization of the part, proceed to inhabit, multiply, and take possession of the part, to its ultimate destruction—just as other microbes have an affinity for the epiphysis of long bones where the blood current is sluggish.

and the inguinal canal empty. There is often pallor and prostration from loss of blood. The bowels are unaffected.

5. Bubo is seldom mistaken for a scrotal tumor, and it is unnecessary to name differential points.

6. An *undescended testicle* is painful, and pressure upon it yields a peculiar sickening sensation. It is found wanting upon the side occupied by the tumor, and the scrotum is imperfectly developed upon the same side. It is sometimes mistaken for a bubonocele.

The Diagnosis of Renal Cancer.

Dr. Jno. A. Octerlony thus writes in the *Jour. Am. Med. Ass.:*

Attention to the following points will generally establish the differential diagnosis:

CANCER OF STOMACH.	CANCER OF KIDNEY.
1. Vomiting is the rule.	1. Generally absent.
2. Hæmatemesis, especially in the form of "coffee-grounds," very common.	2. Very rare.
3. Hæmaturia absent.	3. Hæmaturia generally present.
4. Tumor in epigastrium.	4. In one or the other flank.
5. Tumor small.	5. Tumor often large.
6. Tumor movable.	6. Generally fixed.
7. Tumor descends with diaphragm.	7. Does not descend with diaphragm.

Enlargement of spleen and renal cancer have been confounded (Luna). It is, of course, only when the left kidney is involved. that such a mistake is likely to be made, The two differ as follows:

ENLARGEMENT OF SPLEEN.	RENAL CANCER.
1. Absence of descending colon in front of tumor.	1. Descending colon may be found in front, vertically dividing the tumor in two lateral halves.
2. Border of tumor thin, rigid, smooth, but not rounded.	2. Border often irregular, nodulated, rounded, not thin.
3. Extends upwards under the ribs.	3. Less so.
4. Direction of tumor downwards and inwards.	4. Downwards toward iliac fossa.
5. Very movable.	5. Generally almost or quite immovable.
6. History of malaria or leucocythæmia.	6. Absent.

Hydro-nephrosis and renal cancer also present certain resemblances and dissimilarities, which are brought out in the subjoined table:

RENAL CANCER.	HYDRO-NEPHROSIS.
1. Generally unilateral.	1. Generally unilateral.
2. Tumor hard or irregularly soft.	2. Soft.
3. Rarely and then imperfectly fluctuating.	3. Fluctuating.
4. Tumor permanent.	4. Liable to subside suddenly at times, with copious discharge of urine.
5. Tumor often of enormous size.	5. Not so.
6. Tumor generally fixed.	6. Movable.
7. Does not descend with phragm.	7. Descends with diaphragm.
8. Tumor of rapid growth.	8. More slow.
9. Cachexia.	9. Absent.

The differential diagnosis between cystic degeneration and cancer of the kidney is established by attention to the following points:

CYSTIC DEGENERATION.	CANCER.
1. Bilateral.	1. Generally unilateral.
2. Tumor may be large.	2. Tumor attains an enormous size, much larger than is ever reached in cystic degeneration.
3. Tumor movable; it rises and falls with the diaphragm.	3. Tumor stationary, and does not move with diaphragm.
4. Runs a rather slow course.	4. Runs a more rapid course.
5. No cachexia.	5. Cachexia sets in early, and is well marked.

Various uterine and ovarian enlargements have been confounded with renal cancer.

Malherbe (Soc. Anat., 1872,) relates a case in which cancer of the kidney was mistaken for a fibrous tumor of the uterus. And Dr. Greenhalgh (*St. Barthol. Hosp. Rep.*, vol. lxxxv.,) gives the history of a patient in whom a tumor, supposed to be ovarian, acted as a complication in two pregnancies, and the propriety of removal was about to be entertained when the patient again became pregnant. She died without obvious cause three weeks after delivery at the full term, and the autopsy showed that the supposed ovarian tumor was really the left kidney in a very advanced stage of disease. It weighed twenty-seven pounds three ounces. Pregnancy and renal cancer were mistaken for one another when fœtal diagnosis was not so well understood and practiced as it is now, but at the present such an error could hardly be made or adhered to for any length of time by an intelligent and careful observer.

Besides the case of Lossen, which will be mentioned further on, it happened to Peaslee, of New York, and to Spiegelberg, of Breslau, to make the diagnosis of ovarian tumor, and to open the abdomen, when the disease proved to be renal cancer. Both patients died within three days.

The points involved in the differentiation between the two conditions are:

RENAL CANCER.	OVARIAN TUMOR.
1. Generally unilateral.	1. Generally unilateral.
2. Develops from above.	2. Develops from below.
3. Tumor hard.	3. Soft.
4. Rarely fluctuating.	4. Generally fluctuating.
5. Irregular, nodulated.	5. Generally smooth.
6. Loop of intestines in front of tumor common. Dullness to the outside.	6. Intestines pushed aside, resonance on outside. Dullness central.
7. Aspiration brings pure blood and sometimes cancerous material at point of needle.	7. Aspiration brings away characteristic ovarian fluid.

Hepatic and renal tumors have not seldom been confounded. Rayer and Frerichs both mention cases in which renal cancer had been pronounced cancer of the liver. It is true the two may coëxist, as was observed in one of my own patients; but as a rule, attention to the following points will distinguish them:

Cancer of the liver lies much higher and

generally presents an irregular nodulated border running more or less diagonally across the abdomen; the intestines never lie in front of it. Jaundice is common, hæmaturia is rare. In renal cancer the tumor occupies a lower point, rises vertically and not so high; ascending colon generally lies in front of it. There is an appreciable interspace between the margin of the liver and the upper border of the renal tumor. Jaundice is very rare and hæmaturia common.

Many other diseases from which renal cancer is to be diagnosticated can be mentioned only in passing. Hydatids of kidney, perinephritis, psoas-abscess, enlargement of mesenteric glands, abdominal aneurism, ascites, distension of cæcum and ascending colon, etc.

The judicious employment of purgatives to empty the bowel, the practice of auscultation and percussion, the use of the aspirator and attention to the history of the case, will generally suffice for a correct apprehension of the nature of the disease.

Gangrene of the Penis.

Dr. F. A. Coward thus writes in the *Brit. Med. Jour:*

As cases of gangrene of the penis are somewhat rare, I forward notes of two cases which have come under my care this year.

Case 1. On January 9, J. L., a weaver, aged 35, a married man, consulted me for a swollen and œdematous condition of the penis. He had not suffered at any time from gonorrhœa, syphilis, or stricture. He had had good health, but at times was given to fits of intemperance. He had worked up to the time of consulting me. On the 10th I found him in much the same condition as the day before; the only difference being that there was a slight discoloration on the skin on one side, near the prepuce. On the morning of the 11th, I was surprised to find the whole of the prepuce, and a portion of the skin behind it, one black mass of slough. With the assistance of my friend, Mr. John Martin, I placed the man under chloroform, and slit up the gangrenous mass. I then found that the glans penis was also in a partial state of degeneration; but no signs of chancre, either hard or soft, were to be found, nor could we find any enlargement of the lymphatic glands. From the 11th up to the 17th, the gangrene spread slowly from the extremity to within an inch of the root; and, a line of demarcation having now shown itself, about three-fourths of an inch from the root, on the afternoon of the 17th, again assisted by Mr. Martin, I amputated the penis by means of the thermo-cautery, and the man made a rapid recovery, his temperature never rising above 99°. He returned to work on February 5, and has had no relapse, nor any signs of venereal complaint. There can be little doubt that this was a true case of idiopathic gangrene, due to embolism of the dorsal artery.

Case 2. On April 8, J. J., aged 40, a married man, came to the surgery suffering from acute orchitis of the left testicle, and an inguinal hernia of old standing on the right side. I ordered him to bed, and visited him the next day, the 9th, and found his condition much the same, only that the hernia was not down. On the morning of the 10th, he sent, asking to be seen early, as he was in great pain, and unable to pass urine. My assistant went, and found the penis greatly swollen and œdematous, and twisted upon itself; the scrotum and lower portion of the abdomen were œdematous also, and evidently infiltrated with extravasated urine. He, with difficulty, passed a No. 1 catheter, there being a tight stricture about two inches from the meatus, and drew off over a pint of urine, but retained the catheter in the bladder. On the 11th, the man appeared better. The swelling had somewhat subsided. He was in no pain, and had passed a fair quantity of urine by aid of the catheter. On the 12th, the catheter was removed, and a No. 3 passed and retained. The swelling had gone down considerably, but a slight discoloration was now noticeable on the skin near the prepuce. On the 13th, at noon, he was much depressed. His skin was clammy; he had muttering delirium and flickering pulse; respirations over 40. The penis, near the prepuce, was one gangrenous mass. By 4 in the afternoon, gangrene had spread from the extremity to the root of the penis, and thence over the lower portion of the abdomen; and by 11 the same evening, the last time I saw him, it had reached the umbilicus. He died before morning. Evidently on the 10th, during an effort to pass urine, the urethra must have given way behind the old stricture, and extravasation of urine occurred. The bladder could not have been ruptured, for by the aid of the catheter urine was passed freely up to the time of death.

Tests for the Purity of Milk.

The *Western Druggist* says: What process affords the simplest and most accurate test for determining the quality of milk, was the subject of a paper read before the

Massachusetts Pharmaceutical Association by W. W. Bartlett, who called attention to the various procedures used by adulterators of milk, and discussed various methods of discovering the same, giving preference to Wauklyn's method. Milk should have a specific gravity at 60° F. of 1,029 to 1,033; if fresh, should have a slight acid reaction. Alkaline reaction in alleged fresh milk indicates adulterants; excessive acid reaction indicates lactic fermentation. The cream should be determined by a 100 cc. tube graduated into cubic centimetres and the volume read off at the end of twenty-four hours. The total solids are then determined as follows: If a porcelain capsule be used to evaporate the milk, a small amount of pure white sand should be added to the latter, after having been washed, heated red, cooled, and then weighed with the capsule (the sand breaks the film formed on the drying milk). It is best, however, to use a perfectly flat-bottomed platina capsule, 2¼ inches in diameter and ½ inch deep. The capsule being perfectly balanced on the scales, five grams of milk are carefully weighed into it. The dish is then placed on a water-bath heated till apparently dry (takes about one to one and one-half hours). It is then placed in a hot-air oven and exposed to a heat of 220° F. for half an hour, by which time its weight will be constant. The difference between the weight of the empty capsule and its present weight will be the weight of the solid contents of the milk. The capsule and contents are next placed upon a water bath and boiled with three successive portions of petroleum benzine, decanting off each portion carefully after boiling for a minute. The capsule is then carefully washed off with benzine, dried in the oven, cooled in a desiccator, and quickly weighed; as the fat is removed by this process, this difference between the last weight and the former is the weight of the fat. The other solids ignited at a red heat yield the percentage of inorganic salts. The amount of water present is easily determined. Thirteen per cent. of water found in each sample in excess of 87 per cent., allowed by law, represents one per cent. of added water. The amount of milk sugar may be determined by a standard Fehling's solution or the polariscope; the last yields the best results.

Syphilitic Chorea.

The *Maryland Med. Jour.*, quoting from the *Lancet*, says: A young man in Buenos Ayres, who by his strange contortions had excited the curiosity of the passers-by, recently came under the care of Dr. Franceschi, who was somewhat puzzled by the symptoms. The movements were of a choreic nature, the most characteristic being a contortion of the thoracic, abdominal, and pelvic muscles. The patient's condition became so grave that he could not move out of his room. For a month various methods of treatment were unsuccessfully employed—electricity, sulphur baths, strychnine, hyoscyamine, etc. A consultation was then arranged with Drs. Valdes and Alcorta. The first of these gentlemen remembered having treated the patient six months previously for a chancre, which at the time was not thought to be syphilitic, and had not been treated by mercurials. There were no enlarged inguinal glands or other marks of syphilis; however, it was decided that the chorea might be of syphilitic origin, and therefore Ricord's pills (green iodide of mercury), inunction over the spine of a mercurial and croton ointment, together with Van Swieten's solution (perchloride of mercury) and vinum ferri, were prescribed. In three days salivation occurred, and simultaneously with it the choreic convulsions disappeared. The mercurial treatment was then discontinued, but it was found necessary to resume it, for the convulsions soon began to recur. The salivation subsequently became so distressing that the mercury was again stopped, and the convulsions returned, though not so severely as before. Mercurial and iodide treatment was continued for six months, at the end of which time the patient was completely cured. Dr. Franceschi considers this case especially instructive, as, though various predisposing causes are named in connection with chorea, neither syphilis nor mercurial treatment is mentioned, as far as he can find, by Bouchut, Graves, Jaccoud, Diday, Tardieu, or Trousseau. It has, on the contrary, been stated that mercurialization may act as a factor in its etiology; here, however, is a case in which mercury cured it. The author seems to think that perhaps a hereditary syphilitic taint may sometimes have some effect on the development of chorea, and that, if so, mercury would be the best form of treatment to adopt.

The Cocaine Craze.

In an article entitled "Sensationalism in Therapeutics," Dr. C. H. Hughes (*Weekly Medical Review*) says:

The truth about cocaine is that it is a tonic and stimulating exhilarant of some power in

melancholia, mental depression, and nerve weariness.

That it acts rapidly but much more evanescently than morphia.

That, excessively used, it intoxicates and converts melancholia into mania.

That, given largely in the upright position, it is capable of inducing vertigo, whether, as Dujardin-Beaumetz thinks, by inducing anemia is not proven.

That, as an antidote to alcoholism and its effects, it is not equal to morphia.

That it is not equal to morphia as a tonic in melancholia or as a narcotic in certain states of nervous debility.

That in equal doses it nauseates more certainly than morphia.

That it is not an antidote to meconophaggism, though beneficial if judiciously used and timely abandoned.

That it may be used with advantage, if carefully given, in the withdrawal of opium and the cure of the opium habit, as one of many substitutes, but cannot be alone relied upon.

That it intoxicates some persons and poisons them.

That its continuous use is difficult to break off.

That it is probably capable of developing permanent madness, like similar intoxicants, as a few doses occasion temporary insanity.

That it is a dangerous therapeutic toy, not to be used as a sensational plaything.

That it will probably help to fill rather than deplete the asylums, inebriate and insane, if it should unfortunately come into as general use as the other intoxicants of its class.

As an intoxicant it is more dangerous, if continuously given, than alcohol or opium, and more difficult to abandon.

Gastrostomy for Cancer of the Œsophagus.

In 1880, in Moscow, Dr. Knee founded a private clinic of his own, specially for surgical cases. He has now 16 beds. For the last four years Dr. Knee has treated 27 cases of cancer of the œsophagus. The patients were 25 males and only two females. In the clinic were treated 17 patients, of whom 6 were lost sight of. Gastrostomy had been performed in 13 cases, of which in 10 the result was favorable, and in 3 unfavorable.

The cases with favorable result were as follows:

No. 1. Male, æt. 49, sick 15 months; gastrostomy performed January 2, 1882; lived after operation 9 months; cause of death, cancerous metastasis.

No. 2. Male, æt. 48, sick four months; gastrostomy September 6, 1882; was alive 2 months since, but was lost sight of.

No. 3. Male, æt. 62, sick 5 months; gastrostomy January 21, 1883; lived after operation 5 months and 28 days; cause of death, pleurisy.

No. 4. Male, æt. 40, sick 6 months; gastrostomy August 30, 1883; was seen alive in December, 1883, but was lost sight of afterwards.

No. 5. Male, æt. 50, sick 8 months; gastrostomy October 2, 1883; lived 5 months; cause of death pneumonia.

No. 6. Male, æt. 50, sick 8 months; gastrostomy October 2, 1883; lived after operation 8 months and 17 days; cause of death pneumonia.

No. 7. Male, æt. 62, sick 5 months; gastrostomy January 13, 1884; lived 9 months; cause of death, cancerous diathesis.

No. 8. Male, æt. 41, sick 7 months; gastrostomy February 7, 1884; lived 9 months and 6 days; cause of death, pneumonia.

No. 9. Male, æt. 59, sick 4 months; gastrostomy April 14, 1884; was seen alive July 11, 1884, but afterwards was lost sight of.

No. 10. Male, æt. 56, sick 5 months; gastrostomy July 3, 1884; was seen alive November 6, 1884, but afterwards was lost sight of.

Cases with unfavorable result:

No. 1. Male, æt. 62, sick 12 months; gastrostomy November 11, 1881; died within 36 hours; cause, perforation into the left bronchial tube.

No. 2. Male, æt. 39, sick 6 months; gastrostomy December 28, 1883; died on 8th day, from bleeding.

No. 3. Male, æt. 61, sick 8 months; gastrostomy November 15, 1884; died on twelfth day from exhaustion.

In Europe there are known 56 cases of gastrostomy (except those of Dr. Knee) with favorable result.

Dr. Knee protests emphatically against treatment with bougies or probes in cases of cancer of the œsophagus, for fear of perforation into trachea or bronchi, and also of premature opening of the cancerous tumor. No cicatrization can be hoped for in such cases. Out of 13 patients of Dr. Knee, 6 had a complete stricture of the œsophagus, and 7 could pass only small quantities of fluid. The operative technique adopted by Dr. K. is as follows: A primary incision in the abdominal wall, from 6 to 8 cm. long, from the 8th rib, along the margin of ribs. The peritoneum having been incised, he at-

tached the peritoneal coat to the edges of the wound. Then he extracted a portion of the stomach, and attached it to edges of wound by from 15 to 20 Lembert sutures, taking care that sutures should pass only through the serous coat of the stomach. On having finished this part of operation (laparotomy), the wound is dressed and the patient is ordered to take ice and opium. Four nutritious clysters per day. The wound was dressed again on 6th day. The stomach was opened on 8th or 9th day, and a tube from 5 to 6 mm. introduced. At first only liquid food (milk, wine, egg) was introduced through the fistula, and afterwards scraped raw meat and even roasted meat. Some patients took by fistula about six pounds of food per day. In one case there was an obstinate vomiting, which disappeared only gradually. Complete cicatrization took place in from 18 to 20 days after laparotomy; therefore Dr. Knee removed sutures only at the end of a fortnight.

Malignant Infantile Jaundice of Seven Days' Duration.

Dr. A. B. Hirsh thus writes in the *Polyclinic* for September:

Mrs. J. T. F., aged 28 years, American, was delivered by me, on August 3, 1886, of an eight months' male fœtus, having been for some six months previously under my care for recurring attacks of albuminuria, during the intervals of which both casts and albumen would entirely disappear from the urine. General œdema was present for three weeks prior to confinement, so that she was greatly discommoded. It will be seen that her system was greatly depressed, although persistent efforts were employed to relieve the kidney affection. Labor set in at the beginning of the ninth month of pregnancy. The stage of dilatation lasted fully thirty-six hours, but that of expulsion only a short time. This hardly accounted for the cyanosis present in the child at birth. The latter condition changed in about an hour to the usual congestion of the skin found in the newly-born, and this passed off by next day. Then jaundice set in, and became more marked to the end. The yellow hue of the sclerotic was soon hidden by the deep, passive congestion of the conjunctiva, which, despite treatment, never changed. The lids usually remained closed, and on the last day a puriform discharge oozed between them. Respiration was always feeble, and the infant's cry was more akin to bleating. The extremities remained cold despite the outward warmth applied by cotton batting, hot baths, etc. After the first day the child's attempts at nursing were very feeble, and swallowing became almost out of the question. Death was preceded by chronic spasms. It is to be regretted that no autopsy could be obtained.

The influence of this, as any other cachexia, upon premature birth and viability of the fœtus, is well known, as are also the theories of cholesteremia and of infarct into the renal pyramids in fatal cases of this affection. In describing this case of malignant jaundice in the new-born, it is merely desired to record those objective symptoms which, collectively, may hereafter serve to furnish a definite pathology of the disease, with, possibly, more exact therapeutical indications than are at present known.

Delhi Boil.

Dr. Cunningham has discovered a peculiar parasitic organism in the Delhi boil (*Scientific Memoirs of Medical Officers of the Army of India*, Part I, Calcutta, 1885). The organism in question, brought into view by the use of gentian-violet, was found amidst the lymphoid elements that form the substratum of the boil. The organism is, on an average, larger than a lymph-corpuscle, but great variations as to size and form were met with—some being circular, others elliptical, others lobate. They contain nuclear-like bodies, which have an affinity for the staining material, and in some specimens present an appearance like that of actino-mycosis. The organisms occurred in variable numbers in different specimens, and in some were apparently undergoing division. Their most frequent seat was the layer of granulation tissue beneath the papillary layer of the skin; but in places they occurred within the papillæ, and exceptionally even in the epidermis. They were also met with in the subdermal tissue. No definite conclusion as to their nature could be arrived at; but until their life-history can be studied they might be classed provisionally with the Monadineæ among mycetozoa. As to their connection with the disease, it is obvious, Dr. Cunningham points out, that they cannot gain entrance by a raw surface, since no such condition exists, and the epidermis is abnormally thick and resistant. This very fact, however, suggests the notion of their being causally related to the affection—an idea further borne out by the endemic occurrence of the disease and its connection with water-supply. It is possible that they

gain entrance through the hair follicles and sweat glands, around which the inflammatory changes are most marked and the organisms most abundant. The distribution of the organisms also indicates the need for free excision in the treatment of Delhi boil. "It is quite possible," adds Dr. Cunningham, "that similar changes may be produced by other parasitic organisms, or that the lesions may arise apart from any parasitic agency."

Case of Total Extirpation of Scapula, with Excision of the Head of the Humerus and the Acromial Portion of the Clavicle for Caries, with Final Recovery with good Utility of Arm.

Dr. Schulz, of Sonnenberg in Neumark, reports (*Deutsch. Zeitschr. f. Chir.*) the case of a farm-hand, æt. 16, who was admitted to the Johanniter Hospital in Sonnenburg, August 11, 1884, for pain, redness, and swelling of the shoulder-joint. He had gone to sleep July, 1884, and, on awakening, could not use his arm. Treatment with tr. iodine. After one week incision liberating pus. Fistulæ remained below the spine of scapula and in the internal aspect of the upper third of arm. Movement was greatly impaired; pressure caused pain; temperature 40° C.; pulse feeble; occasional fainting spells.

Treatment.—Tonic, eggs, wine, quinine, phosphates; repeated incision and drainage: arm maintained in fixed position.

Subsequently improvement set in. But incision of an abscess above the spine of the scapula became necessary; the focus was scraped out with the sharp spoon. Roughened bone could be felt over the whole of the scapula with probes, and joint-affection was established.

September 1. Arsenic given, with general improvement; subsidence of suppuration; increase of appetite. Soon, however, another abscess appeared near the acromion demanding incision.

December 12. Extirpation of scapula; incision from spine to angle; subscapular artery tied; head of humerus exsected, as well as acromial end of clavicle, both being carious. Sublimate dressings; reactionary temperature 38.0°; subsequent reconvalescence.

February 10. Patient up and about; can move fingers and forearm, and rotate and swing upper arm, but cannot abduct it.

May 6. Dismissed with a support; can write; was seen after five months again, still improving.

Some remarks are added, and a brief mention of twelve other cases is made.

The Treatment of Chronic Abscesses by Injections of an Ethereal Solution of Iodoform.

Verchère (*Rev. de Chir.*, June, 1886,) reports twenty-three cases which were treated in this manner, and gives the following directions in regard to the operation: The solutions of iodoform should be of varying strength, one of five per cent. being used for large abscesses, and one of ten per cent. for small ones, while small, superficial abscesses may be filled with a saturated solution. If the skin over the abscess is not affected, the needle of a hypodermic syringe is introduced in an oblique direction, so as to form a valvular fold; the pus is then drawn off, and the iodoform solution is injected. If, however, the skin over the abscess is quite thin, the pus is removed with an aspirator, and the opening made by the needle is sealed with collodion, after which a hypodermic-syringe needle is inserted into the abscess cavity, and the injection is made as before. The object of these manœuvres is to prevent the ether from escaping through the puncture, as it at once tends to do on becoming volatilized. As the solution volatilizes, the iodoform is deposited over the entire inner surface of the abscess, and is slowly absorbed—so slowly in fact that the danger of poisoning by the drug is said to be very slight. The phenomena observed after an injection are, briefly, as follows: Rapid and sometimes excessive swelling results from the volatilization of the ether, but this soon subsides. If the skin over the abscesss is healthy, the abscess cavity will speedily be replaced by indurated tissue, without the occurrence of any external change. If the skin is already inflamed, it will separate in a few days in the form of a yellowish slough, after which healing will occur by granulation, the resulting cicatrix being slight. The advantages alleged for this method of treatment are the perfect safety of the operation, the rapidity of the cure, the fact that the patient is not confined to his bed during the treatment, and the non-recurrence of the abscess.

Conception of Male Children at the Time of the Post-Menstrual Anæmia.

The *Therapeutic Gazette* says that Dr. Camillo Fürst, of Graz, publishes in the *Archiv für Gynœcologie*, 1886, xxviii., 1, p. 14, a contribution to the interesting and frequently discussed question, When and how is the sex of the conception product determined? In the first section of the paper, which treats of "the time and causes of the determination of the sex in general," Fürst

proposes certain maxims which, though not new, will interest our readers. According to the author we find a surplus of male conceptions in the working classes and country inhabitants as compared with the well-to-do people and the inhabitants of cities. Likewise, we can look for the surplus of male infants during hard times and the concomitant rise of food-prices, and before the ultimate extinction of a race. If a deficient nutrition of the procreators produces a surplus of male children, our author continues to argue, we can be certain that also the state of nutrition of the fecundated ovum, especially shortly after conception, will influence the sexual differentiation. And as after menstruation the vessels of the genital organs assume an ischæmatous character—forming the so-called post-menstrual anæmia—Fürst concludes that conceptions taking place immediately or shortly after menstruation will give a surplus of males, on account of a relatively bad nutrition of the fecundated ovum. To strengthen his theory, the author utilizes the statements of women confined in maternities, who mostly with astonishing certainty could remember the end of the last menstruation and the day of conception. The statistics of the mentioned institutions show a very considerable surplus of male children for the first four or five days following menstruation, and a surplus of female ones for the succeeding period.

Case of Cholecystotomy.

Dr. A. Landerer, of Leipsic, reports (*Münchener Med. Wochenschrift*) the case of the wife of a shoemaker, æt. 35, who suffered for about eight months from severe pains in in the region of the liver. No stones were passed; no jaundice occurred; the pains were intermittent in character. A tumor of the size of a child's head, with irregular surface and hard to the feel, could be made out in conjunction with the liver and participating in its movements. The lower portion gave a tympanitic note, and the tumor, slightly movable under the integument, was painful on pressure, especially near its upper part. Urine and pelvic organs normal.

Incision parallel to the median line over the tumor revealed the tumor adherent to the transverse colon and covered by hepatic tissue, and connected with the meso-colon behind. Tapping produced mucus and pus, and verified the diagnosis of empyema of the gall-bladder.

As extirpation was impossible, the author stitched the liver to the abdominal wall around the incision by means of five silk sutures, and applied sublimate and iodoform dressings. After six days, during which no febrile reaction occurred, a large trocar was inserted into the gall-bladder through 2½ ctm. of liver tissue, and drainage established. Subsequently the opening was enlarged by Pacquelin's cautery.

The patient made a good recovery, the pains were effectually cured, and only a fistula remained, through which only a few drops of ropy mucus were daily discharged.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Dr. T. D. Crothers, of Hartford, Conn., has issued as a brochure his medico-legal study of the Otto case. It is an instructive paper.

——Dr. Louis J. Lautenbach, of Philadelphia, sends a paper containing his ophthalmoscopic examination of the insane at the Norristown State Hospital and at the Philadelphia Hospital. He advances no inferences as yet.

——In a recent reprint, Dr. W. A. Edwards reports a case of intestinal casts and discusses the disease sometimes called "membranous enteritis." He enters very fully into the bibliography of the affection.

——Dr. F. B. Stephenson, U. S. Navy, in a learned article entitled "Arabic and Hebrew in Anatomy," traces many of the terms now or formerly used in this science to their origin in the languages named. It is a curious and interesting study of this remote branch of medical literature.

——In a paper read before the Social Science Association, Hon. Robert Adams, Jr., advocates the restoration of corporal punisement by flagellation; in other words, the old-fashioned whipping-post, for the benefit of those men who shall be convicted of beating their wives. We heartily second the motion.

—The *Brit. Med. Jour.* tells of a scybalum so large that in order to extract it, it was necessary to give the patient chloroform and apply Simpson's short forceps. The patient, a woman, suffered from delusions which appeared to be due directly to the intestinal accumulations.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

TREATMENT OF TYPHOID FEVER.

Since the treatment of this peculiar disease is necessarily, to a great extent, the treatment of each individual case, it is well to know how our great men treat their cases. The following is a brief outline of the plan of treatment which is carried out under the directions of Prof. Draper at the New York Hospital: There can be no doubt that quinine in large doses acts as a powerful agent in reducing high temperature in typhoid fever. In small or moderate doses, such as 20 grains in the course of twenty-four hours, little or no antipyretic effect will be obtained in most cases. But if used at all for this purpose, it should be in heroic doses, and 30, 40, 50, or even 100 grains in the course of twenty-four hours will often be necessary to produce the desired effect. With the reduction of temperature which these large doses produces, there is also an improvement in the quality and frequency of the pulse and respirations, and the restlessness is quieted, and the delirium disappears, and the expression of the face improves, and the patient feels better. In this condition of high fever it is much more difficult to produce cinchonism than in non-febrile states, and hence quinine may be given with more boldness in urgent cases. But many of the milder cases of typhoid fever need no antiphlogistic treatment at any time; for this is a self-limiting disease, and it often runs its whole course favorably till it ends in recovery.

Alcohol is unquestionably an antipyretic in all cases where there is a high grade of fever, and it certainly does reduce temperature. However, its utility in fever is not confined to its antipyretic effect, but it also does good by sustaining and stimulating the heart's action, and by furnishing the patient with an easily digestible food which he can assimilate, and by supplying him with a sort of potential energy which lessens the consumption of his own tissues. A striking peculiarity of alcohol when used in conditions of high fever is the fact that it is practically impossible to intoxicate the patient. This is probably because the ability to digest it is now greatly increased, and so it is all consumed as food and does not circulate in the system as alcohol, and hence it does not irritate the nerve centres. Sometimes it is necessary to give from 24 to 36 ounces of whisky in the course of twenty-four hours, and yet the patient will show no signs of intoxication. Nevertheless, there are some cases where it is quite possible to do harm by the free administration of alcohol. The rule is that if by its use the irritability and

frequency of the pulse are increased, and the delirium becomes more active, and the tongue, instead of moistening, becomes more dry, and if tremulousness, subsultus, and restlessness are aggravated rather than diminished, the alcohol is doing harm, and should be withheld. Where large quantities have been used to advantage during the height of the fever, the amount given should be gradually diminished as the febrile symptoms lessen and the pulse and temperature fall.

As to the form of administering this remedy, brandy, whisky, and gin are all more easily digested than wines; but pure alcohol itself is probably preferable to any of its preparations, for it is the essential part in them all, and it is not likely that the others do any good. To avoid its local effects upon the stomach it should be administered with food, and the best plan of all is to mingle it with milk if the patient will take it so. The quantity to be administered should be regulated by the severity of the case, and by its effects in relieving the symptoms. Four ounces in the course of twenty-four hours may be enough, or a quart or more may be required. The period of twenty-four hours in which the largest amount should be administered is between the hours of 6 p. m. and 6 a. m., for this is the time when the vital powers are at their lowest and the danger of exhaustion is greatest.

Besides alcohol, sometimes carbonate of ammonia, ether, or other diffusible stimulants may be necessary to tide the patient over a temporary or special danger, and digitalis may also at times be used to advantage to stimulate the heart's action. Where insomnia and great nervous irritability are persistent, opium may be administered in moderate doses. These are the general principles to be carried out in the treatment of typhoid fever, and any additional indications should be carried out as they arise.

AN IMPORTANT MEDICO-LEGAL CASE.

It has been usually conceded that a man cannot shoot himself in the head without presenting evidences of the proximity of the weapon, to be found in the scorched and blackened skin, singed hair, and presence of grains of powder, and these facts have been usually considered to establish the question as to whether death from a shot wound of the head has been suicidal or homicidal. But it would seem, from a very interesting case which Dr. D. B. N. Fish reports in the *Boston M. and S. Journal* (September 23), that this conclusion is erroneous. In the case in question a man was found dead with a bullet wound in the back of his head, and as there were no signs of the proximity of the pistol when discharged, it was at first supposed that he had been murdered. But there were collateral circumstances which suggested the theory that it was a case of suicide wherein the suicide desired to create the impression that he had been murdered. So Dr. F. set to work to find out whether a man could shoot himself in the head when holding the pistol more than eighteen inches away, for within that distance the scorching and singeing will always be found. It was noted that there was a long string attached to the stock of the pistol, and herein was found the clue to the mystery. Dr. F. discovered that if a man were to tie a string as this was tied, he could, by passing it under his foot, steady the pistol when held at arm's length, holding the pistol somewhat as one would hold a pen. Then pointing the pistol at his right eye, after securing his aim, he could, by turning his head around towards the left shoulder, shoot himself in the back of the head, making such a wound as had been found in this case. At the same time the pistol would be so far away that no scorching would occur. The theory of suicide thus explainable was endorsed by the fact that the man was in financial trouble and had a heavy insurance on his life. The jury rendered a verdict of suicide. The importance of this case from a medico-legal point of view is very great, as can be readily perceived.

NOTES AND COMMENTS.

Cocaine in Angina Pectoris.

Prof. Laschkewitch has found good results from the internal administration of cocaine (in doses of one-half to one-third of a grain three or four times daily) in cases of angina. It does not cut short an attack, but diminishes its intensity, and after a few days' consecutive administration it gradually diminishes the force and duration of the seizures until they may wholly disappear (*Revue de Méd.*, August, 1886). He details four cases; one was that of a man thirty-five years of age, the subject of aortic regurgitation and dilatation of the aorta. Anginal attacks occurred as frequently as eight times daily, and were of a characteristic kind. He was obliged to keep his bed, but the attacks also occurred during the night, preventing sleep. The disease had lasted two years, and had not been

much benefited by oxygen inhalation. Half-grain doses of cocaine were prescribed, with the result that the attacks became less frequent and shorter, eventually disappearing. The patient died subsequently of an infectious disease. Another case was that of a man aged sixty-three, with mitral disease, aortic dilatation and general arterial sclerosis. Anginal attacks had occurred during the past six months on physical or mental exertion, and were only subdued by morphia. Here, again, cocaine acted admirably, the angina ceasing after three days' administration. In a third case the patient, aged fifty-eight, presented marked arterio-sclerosis; the angina disappeared after two days' administration of one-third of a grain four times a day. The fourth case, a man about forty years of age, was one of aortic regurgitation with marked dilatation of the aorta; and the administration of cocaine speedily cut short the anginal attacks, which had become severe and frequent. Prof. Laschkewitch says that the remedy produces slowing of the pulse, which gains in volume; at the same time the quantity of urine is increased. He thinks that by combining this treatment with that by inhalation of oxygen, which acts immediately in an attack, the anginal seizure may be arrested, and its reappearance prevented.

Hypodermic Injections of Calomel in Syphilis.

Professor Stukovenkoff reports very favorably in the "Zemskaya Meditsina" on the anti-syphilitic treatment recommended by Professor Scarenzio. This consists of the hypodermic injection of calomel suspended in glycerine, or, better still, in a mucilage of gum arabic. The localities chosen for the punctures are the gluteal regions. A grain and a half of calomel is injected on each side, making a total dose of three grains. This double injection is repeated at the end of two or three weeks, and that, as a rule, concludes the treatment, for it is rarely necessary to have recourse to a third dose. The author has practiced these injections for a whole year, and is convinced that they never give rise to serious evil consequences. In two or three days after the injection a swelling appears at the seat of puncture, but the skin is not reddened, and it diminishes in three days and passes away in a fortnight, never becoming an abscess. The syphilitic symptoms rapidly vanish; gingivitis and salivation never occur. Comparing this method of treatment with that of inunction with mercurial ointment, Professor Stukovenkoff says that from three to nine grains of calomel injected in the course of from four to six weeks are equivalent to from thirty to forty inunctions of half a drachm of grey ointment. This plan has the advantages of simplicity, convenience, and of extreme cheapness. The mercury can be detected in the urine from two to four weeks after the commencement of the treatment, or somewhat later, and in smaller quantity than when other methods of mercurial treatment are employed. Before the injection is given, it is important to shake up the mixture well, also to see that it is quite white, as a greyish tinge indicates that the calomel is being partially reduced, and that the preparation is unfit for use.

Etiology and Treatment of Diphtheria.

M. Delthill, of Nogent, in an interesting communication read in the Nancy Congress, gave an account of the results of his method of treating diphtheria by the fumes of turpentine and coal-tar, with local applications of turpentine. Of 134 cases so treated 126 were cured, and prophylactic measures of the same nature being rigorously enforced, only three mild cases of infection occurred amongst 670 attendants. Amongst other observations, he found that the saliva of diphtheritic patients is always acid, that the incubation period is about five days, and that diphtheritic matter which has not been destroyed preserves its infecting power for more than a year; also, that the disease may "vegetate in a chronic manner" for several months in an individual. Perhaps, however, the most interesting part of M. Delthill's paper and of the discussion which followed related to the connection between diphtheria in human beings and epizoötic diseases. M. Delthill mentioned the case of a child with diphtheria at a farm house, where upon inquiry he found that two months previously to the child's illness the fowls had died of the pip (*pépie*), and that the pigeons had suffered from the same disease. The child had been in the habit of playing in the farm yard where the fowls were kept. M. Bouchard mentioned that he, too, had had a case of diphtheria in a farm house near Paris, where all the fowls had died of the pip. He remarked that in England the pip in fowls is called croup, and that he had no doubt that it had some connection with diphtheria in the human subject. M. Delthill referred likewise in his paper to intestinal diphtheria, the existence of which was undoubted in the human subject, and of frequent occurrence in the calf.

The Intra-Uterine Galvano-Cautery.

Dr. P. Landowski spoke at the recent Congress at Nancy in favor of the action of the electro-cautery in membranous dysmenorrhœa. He expressed his belief that though this condition is doubtless chiefly met with in women who suffer from cachexia or some general disease, still the general condition is very frequently the consequence rather than the cause of the uterine disorder. He mentioned two cases in which he had applied the galvano-cautery, the os being first dilated, and the time chosen being five or six days after the cessation of menstruation. In one of the two cases a complete cure resulted. In the other the pain accompanying menstruation was relieved, but a piece of membrane the size of a penny was expelled at each recurrence of the period. This was probably due to a portion of the intra-uterine wall having been insufficiently touched with the cautery. At the same congress M. Apostoli stated that he had employed the intra-uterine galvano-cautery in a large number of cases of chronic metritis and endometritis with very great success. He does not confine the patient to bed during the intervals between the applications, and improvement very quickly follows the first few cauterizations. The author compares this method with that of scraping the intra-uterine wall with a sharp spoon, and considers that it has the advantages over the latter of being capable of exact graduation, of being more easily localized, and of not being so instantaneous. The result of the cauterizations is to cause the formation of a new and healthy mucous membrane.

Chylous Ascites.

The existence of cases of chylous ascites has been called in question by many observers. Some have asserted that all reported cases of this condition were merely of an inflammatory or cancerous nature, in which the products of the morbid processes had undergone intense fatty degeneration. M. Guinochet, of the Hôpital Tenon, has endeavored to set this question at rest, and apparently satisfactorily. A patient suffering from a peritoneal effusion, believed to be largely reinforced by the escape of normal chyle into the serous sac, was experimented upon in the following fashion: Two punctures were made, partly to relieve tension and also to ascertain the chemical composition of the ascitic fluid. Thus the chemistry of the fluid was determined whilst the patient existed on ordinary diet. Before ascertaining whether any modification of the diet would be followed by a corresponding change in the chemistry of the ascitic fluid, the patient was placed upon milk alone, in which as much butter was emulsionized as the patient could tolerate. If the peritoneal effusion were really derived from the lymphatics, the fluid withdrawn after the administration of a diet so rich in fats as that mentioned should exhibit corresponding changes, not only in an actual increase of the fat, but also in the presence of butyrine—an article which does not occur normally in ordinary human fat, but which would be present in the chyle if butter were an article of consumption. The analysis made by M. Guinochet fully satisfied these requirements.

Note on the Value of Corrosive Sublimate Solutions in Ophthalmic Operations.

In the *Brit. Med. Jour.*, Dr. J. Crawford Renton says:

From the beginning of October, 1885, until the end of June, 1886, in every ophthalmic operation, I have adopted the precaution of bathing the eye with a solution of corrosive sublimate, strength 1 to 5,000, whenever the superficial parts of the eye were to be operated on, and 1 in 2,000 in cases of evisceration, operations on the eyelids, etc.

One hundred and fifty-two operations have been performed, and these include 23 operations for cataract, 34 iridectomies, 11 cauterizations for ulcer of the cornea, 8 evisceerations, 12 tenotomies for strabismus, 2 trephinings of the cornea for conical cornea, and 35 in which the canaliculus was slit open. In none of these did inflammation and suppuration follow; this fact I cannot but regard as a testimony to the value of the antiseptic employed, all the more so as in every previous winter I have invariably seen eyes destroyed by acute suppuration after very slight operations. Cocaine solution (4 per cent.) was used regularly along with the sublimate solution, and I have not as yet been able to satisfy myself that any harm has accrued from it.

The above results confirm the observations of several continental ophthalmic surgeons, and also those of Mr. Berry, given in the *Ophthalmological Review* for October, 1885.

The Manufacture of Quinine by Synthesis.

The *Lancet* tells us that a remarkable discovery, by which the price of quinine may be reduced to something like 15 cents per ounce, has been made by Mr. Cresswell Hew-

ett. The synthetical manufacture of quinine was first suggested to Mr. Hewett in 1869 by the late Dr. Mattheson, of St. Bartholomew's Hospital, whilst giving his assistance in a course of experiments in connection with apomorphia. Subsequently, Prof. Parkes, of Netley, aided with his advice, and to these gentlemen, rather than to himself, Mr. Cresswell Hewett modestly explains that the process is due. The importance of this discovery is rendered greater by the fact that, while hitherto we have been depending for our quinine on the cultivation of the cinchona tree, from whose bark only about 2 per cent. of good quinine can be extracted, 98 per cent. being valueless, the drug can now be manufactured without limit by a very simple process, from an article which can always be got in abundance in any part of the world. Mr. Hewett intends to put himself in communication with the British government, who annually spend in India alone about $300,000 in the cultivation of the cinchona tree.

Elixir Iron Pyrophosphate, Quinine and Strychnine.

Dr. C. R. Bechmann, of Fountain City, Wisconsin, says that the following formula will not precipitate by long standing:

℞.	Quinine sulphate,	120 grains.
	Strychnine sulphate,	2 "
	Iron pyrophosphate,	240 "
	Sodium or ammonium citrate,	60 "
	Alcohol,	2 fl. oz.
	Water,	1 fl. oz.
	Glycerin,	3 fl. oz.
	Simple elixir enough to make	15 fl. oz.

Put the quinine and strychnine in a flask, pour on the alcohol and 5 fluid ounces of simple elixir, then place the flask in hot water, shaking occasionally, until dissolved. Dissolve the iron in the water without heat, then add the sodium (or ammonium) citrate and the glycerin. Pour this solution into the alkaloid solution flask and shake well. When cold add enough simple elixir to bring the quantity up to fifteen fluid ounces. An elixir made three months ago and subjected to 41° F. has remained as clear as when first made.

Addison's Disease in a New-born Infant.

Dr. E. Belaïeff, of Voronej, details in the *Meditzenskoie Obozreine*, No. 1, 1886, a unique case of Addison's disease in a new-born male infant. No case occurring in a child younger than three years of age has ever been recorded. The child had been deserted, and was found lying on the pavement. It appeared to be about seven days old. The integuments were slightly yellowish with a grey tint. Later on, the yellowish discoloration disappeared, while the skin gradually assumed a dirty grey color, which was most intense on the back and belly, especially around the navel. Notwithstanding a good appetite, the infant steadily became prostrated and emaciated, and fifty-three days after admission died in an unconscious state during a paroxysm of tonic and clonic convulsions. There was no fever from the beginning to the end. At the necropsy both supra-renal capsules were found considerably enlarged (1 x ¾ inch), their upper two-thirds being transformed into an aggregate of thin-walled, semi-translucent cysts, the size of which varied from that of a pin's head to a small cherry. The cysts contained clear serous fluid.

Treatment of Recent Abdominal Wounds with Hernia of the Omentum.

Dr. H. Hartmann calls attention to the fact (*Revue de Chirurgie*) that, although French surgeons have adopted advanced views with regard to abdominal surgery in general, they still hold the method of allowing omentum, protruding from an abdominal wound, to cure itself by sloughing off, and then proceeds to give a detailed criticism of the authorities for this method, showing the crudeness of their reasoning, and that the failures of the method of ligature and return to the abdominal cavity, which caused its former repudiation, were due not to any defect in the method itself, but to faults of its application, and recites three sucessful cases to show the perfect safety of ligaturing the protruding part and dropping it back into the abdominal cavity, all under careful antiseptic precautions, by which a surer, more rapid and more generally satisfactory cure was obtained than was possible by the expectant plan.

Fall of 110 Feet; Slight Injury.

J. S., aged about forty, and weighing fourteen stone, on May 14, fell a distance of 110 feet from the steeple of a church, in course of building, the total height of the spire being 130 feet, and the fall occurring when he was within twenty feet of the top. In his descent, he broke a scaffold pole in two, and then fell through the wooden roof of an engine-house below, breaking several planks and two strong joists, on to some sacks of cement inside. He was unconscious when

picked up, but became sensible in a short time; and, on examination, by Dr. J. S. Parrott, who reports the case in the *Brit. Med. Jour.*, was found only to have dislocated the left metacarpals from the carpus, to have broken the left tibia just above the ankle, and to have sustained some bruises about the back and hips. On May 26, the leg being in plaster-of-Paris, he was able to leave for his home twelve days after the accident.

The Nature of Jaundice.

Following in the lines of M. Chauffard, Professor Kelsch, of Val de Grace, writes in support of the specific nature and infective origin of catarrhal jaundice (*Revue de Méd.*, August, 1886). He confirms the clinical observations of M. Chauffard, especially as to the urinary excretion, but is unwilling to accept the doctrine that the condition is due to ptomaines formed in the intestinal tract, regarding an external agent as more probable. The observation of epidemics of jaundice in the army, of which he records instances, points to the conclusion that they are due to telluric conditions, and therein establishes a link between catarrhal jaundice and malignant jaundice. The latter is mostly admitted to be due to foul water supply or bad drainage; and both varieties are frequently associated in epidemics. M. Kelsch, indeed, avers that the simple and malignant forms are one and the same affection, and therefore sums up his belief in the propositions that—

1. Sporadic or epidemic catarrhal icterus is a specific, infective disease.

2. That the infective agent is developed outside the organism.

3. That it is generated in marshes and in soil abounding in animal and vegetable matter.

4. That owning thus a common origin with malaria and typhoid fever, the coincicidence of epidemics of jaundice with ague and typhoid is explained.

Trouve's Electric Sound for Foreign Bodies.

M. Pollailon gave an account before the Académie de Médecine of an operation which he performed on a man who swallowed a table-fork. There was some difficulty in detecting the exact position of the foreign body; palpation and the introduction of an œsophageal sound gave but little result; but the sound of M. Trouvé, to which is attached an electric bell, solved the difficulty. An incision was then made from the ninth rib of the left side, a quarter of an inch from the costal cartilage down towards the umbilicus for three inches; the peritoneum was opened, and the anterior wall of the stomach was drawn to the abdominal opening and incised to the extent of an inch, the fork was seized with a forceps and easily withdrawn, the wound was ligatured with catgut, and the stomach abandoned. The external incision was treated in the ordinary way, and the patient did well.

The Action of Antipyrin and Thallin.

"Taking all things into consideration," says Mr. Raymond Johnson in the *Lancet*, "it seems to me that the evidence is strongly in favor of antipyrin. Any slight advantages which thallin may possess are more than counterbalanced by the transitory nature of its action, the frequently repeated doses which are therefore necessary, and the great liability to the occurrence of shivering or rigors. This conclusion agrees with that of most German observers. Unless, therefore, future investigations shall disclose some yet undiscovered advantages in thallin, we may, I think, decide to employ antipyrin in preference to it, in any case in which a rapid antipyretic effect is desired. Still more is antipyrin to be preferred in cases such as phthisis, where a long-continued use of the drug is necessary. Regarded as a purely symptomatic remedy, the unanimous verdict is that antipyrin is a most efficient agent."

Epileptoid Convulsions Following a Gunshot Injury of the Brain.

Prengrueber (*Bull. de la Soc. de Chir.*, July, 1886,) reports an interesting case of brain injury, due to a pistol-shot, in which the ball entered the middle part of the temporal fossa. During the first three days after the injury, no symptoms were observed except general prostration accompanied by a subnormal temperature. On the fourth day the patient had several epileptoid attacks, whereupon the writer exposed the cerebral wound and removed several splinters which were buried in the brain-substance. An attempt was made to reach the ball with a probe, but it could not be touched. The spasms did not return, and the patient made a perfect recovery.

Papilloma of the Trachea Removed Laryngoscopically.

Dr. C. Labus records, in the *Monatsschrift für Ohren-Heilkunde*, No. 4, 1886, the case of a man, aged sixty-three, who had suffered for nearly two years from difficulty of respiration and other signs of obstruction

in the air-passage. With the laryngoscope a tumor could be seen nearly filling the trachea and growing at the level of the fifth tracheal cartilage. By means of a peculiar forceps the tumor was torn away piecemeal. In seven sittings sixty pieces were removed, which together had a volume of four cubic centimetres. The patient experienced immediate relief, and four months after the operation, although he occasionally expectorated little pieces of the tumor, his respiration was easy, and he could run and ascend stairs without difficulty. On microscopical examination of the pieces removed, the tumor was found to be a papilloma racemosum.

Lanolin.

On the occasion of the reading of a paper by Dr. Thomas G. Morton, on "Lanolin," before the College of Physicians, Philadelphia, Dr. Keen bore the following testimony to its use and value. He observed: "I have used lanolin in several instances during the last week or ten days. One case was that of a child, eight years of age, with an enlarged gland under the jaw, the size of an English walnut. I prescribed iodine, two grains to the drachm of lanolin. I saw the child a week ago, and the gland had almost entirely disappeared. There was a more rapid disappearance than I have ever seen from other iodine applications. This," he observes, "is the only case in which I have had any results, although I have used it in a number of instances, and like it very well."

The Elixir of Life.

According to Dr. Burggraëve, of the University of Ghent, the great panacea for all ills is common salt. According to his theory, salt is the great regulating agent. If the blood be too rich, salt will clarify it; if it be too poor, salt will strengthen it and furnish it with the necessary elements. He estimates that the quantity of salt which every adult in ordinary health should consume daily is two-thirds of an ounce, and he goes the length of saying that if everybody would only take salt, centenarians would become almost as common as new-born babes. What has become of all the centenarians?

The Significance of Collapsed Intestine in Laparotomy for Intestinal Obstruction.

Dr. J. E. Michael, of Baltimore, referring to a statement (*Med. News*) that a dilated intestine would indicate that the cause of the obstruction is lower down, while a collapsed intestine can only be expected on the peripheral side of the obstruction, the writer quotes two cases, which had come under his observation, in which the small intestine was collapsed while there was an obstruction at the sigmoid flexure, to show that the proposition is not strictly correct or invariably true.

Recrudescence of Typhoid in the Same Individual.

At the Congrès de l'Association Francaise pour l'Avancement des Sciences, M. Dehayes spoke on a case of typhoid fever which attacked the same individual a second time after a lengthy interval, and considered that this affection, as well as other contagious maladies, did not render the person proof against recurrences, and in this view he was supported by several of his colleagues.

Correspondence.

Morphia, Hypodermically, for Post-partum Hemorrhage.

Eds. Med. and Surg. Reporter:

I simply desire to add my testimony to the statement of Dr. M. S. McMahan, that morphia, hypodermically, is the remedy for post-partum hemorrhage. I have employed it for nearly twenty years, and regard it as not only superior to any other remedy, but of more value, and entitled, under all conditions of the patient, to more implicit confidence than all other agents combined. My rule is to charge my syringe during the progress of labor with one-fourth grain of morphia, and place it where it can be called into service at a moment's notice. If a woman is pale and nervous, with a rapid pulse, at any time within two hours after delivery, though the uterus be firmly contracted to its smallest dimensions, then is the time to strike with the morphia without waiting for the hemorrhage. I regard post-partum hemorrhage as a mere result of disturbed nerve forces. Have often seen the characteristic pallor and anxious countenance, with feeble, flying pulse, and heard the startling sigh before the uterus had begun to relax.

Opium to the rescue, in this moment of peril. If it can only reach the nervous centres before the uterus yields its grip, the equilibrium will be restored, the hemorrhage will be stayed, and the woman will be happy in twenty minutes. Hot water, chunks of ice, sponges saturated with vinegar, or the rough hand of the doctor thrust into the

uterus, are cruelties involving dangerous and often fatal delay. B. F. Ward, M. D.
Winona, Miss.

News and Miscellany.

The Philanthropy of Dr. Wakley.

In the course of its obituary notice of Dr. James G. Wakley, late editor of the *Lancet*, the *Brit. Med. Jour.* says:

"Dr. Wakley's presence was, of course, familiar in metropolitan professional circles. His chief inclinations, however, during his leisure, were in the direction of occupations that compose the outdoor life of an English gentleman. These he thoroughly enjoyed, for he was a keen sportsman. But, although he will be missed in many ways, it is certain that his loss will by none be more keenly felt than by the poor of his neighborhood, for whose wants and hardships he had ever constant care and consideration. Of him it might be said, in words which have been applied to his father: 'Indeed, in all subjects relating to the poor and helpless, no champion who ever rose for them was more chivalrous than the founder of the *Lancet*. The people were his care. He inquired into the condition of their homes; he sent his commissioners into the workhouses; he supported the parochial medical officers in all that was fair, laudable, and humane.' Certainly, in all these respects, the deceased was the worthy son of a worthy father.

"For it is probable that his benevolence to the poor will remain to be remembered as his chief characteristic. Men will for long tell, as is now done by those who knew him intimately, of the stream of active benevolence which he constantly dispensed. For instance, he would start off on a Sunday morning on horseback, armed with a large number of orders for groceries, bread, flour, meat, coals, etc., which he would distribute to those whom he considered necessitous. He constantly paid the rents of many poor; and, that they might not altogether lose his benefactions after his decease, he has arranged that the rents of fifty or sixty elderly persons shall be paid during their lives out of his estate."

Diseases of Syria.

M. de Brun, Professor in the Medical Faculty of Beyrouth, stated at a recent meeting of the Académie de Médecine, that malaria is the affection most frequently met with in Syria; it is observed both inland and on the coast; it is most prevalent on the plain of Becka. Dr. de Brun has seen infants attacked with acute paludism, accompanied with dyspnœa, which, within an hour, resembled croup at an advanced stage. On examining the throat, nothing was observed. Generally, after four or six hours' suffering, the condition suddenly and rapidly improves, and the little patient regains health without passing through a stage of convalescence. This form of malaria is sometimes accompanied with violent laryngeal œdema; and, in some instances, there is a nucleus of pulmonary œdema. Laryngeal symptoms may be absent. Apparently, when death ensues, it results from arrest of the functions of the medulla oblongata. Sulphate of quinine prevents a second attack of malaria. After malaria, syphilis is the most frequent affection. The Mahommedans, although they represent only the fourth part of the entire population, furnish the greatest proportion of the cases. Hereditary syphilis is very frequent. Dr. Brun rarely met with the lesions described by Mr. Hutchinson. The prevalent affections of the alimentary canal are excessive and frequent diarrhœa, dysenteric affections, and especially dilatation of the stomach, resulting from unwholesome food and from indulgence in alcohol. Arack, or raki, is the beverage generally drunk. Dr. de Brun has observed a considerable number of parasites in the alimentary canal, especially tænia inermis. He found that a preparation of cocoa was efficacious in many instances. The sufferers had taken vermifuges, but without benefit, for them. Pulmonary emphysema is very general, in consequence of excess in smoking. Ophthalmia is also very frequent, also the following diseases: Hepatic congestion, gravel, calculi of the bladder, leprosy, elephantiasis, the Aleppo boil, eruptive fevers, typhoid fever, whooping-cough, diphtheria, occasional epidemics of dengue fever, and, in summer, a special form of erythema, known as sweat-spot (*bouton de sueur*). Nervous disorders are very rare.

A Powerful Bottle.

The following story is told in *Harper's Magazine* for October of the General Traffic Manager of a Southern railroad. Some time ago, as he was returning to New York from the South, the train on which he was riding stopped at Elizabeth, and among the passengers who boarded it was a richly dressed lady, who entered the car in which he sat, and anxiously glanced around for a seat. The train was crowded, and Mr. O—— im-

mediately arose and gave the lady his (the outer) half of the seat, and stood in the aisle near by. When Newark was reached, the gentleman who occupied the other half got out and left the car. The lady at once arose, as if to give Mr. O—— his portion of the seat, shook out her skirts, seated herself again with her back to the aisle, and put her little hand-satchel on the other half of the seat. By this time many of the passengers had become interested in the situation. When the train reached that portion of the meadows between Newark and Jersey City on which the phosphate works are situated, the terrible stench, so familiar to those who habitually travel on the Pennsylvania and Morris and Essex railroads, penetrated the cars. Quick as thought, the lady seized her satchel, got out a bottle of smelling-salts, and clapped it to her nose. Mr. O—— saw this, and leaning over, he said to a couple of gentlemen in the seat immediately behind her, "Gentlemen, what in the name of heaven has that woman got in that bottle?"

The lady instantly turned, and said, "*It is not this bottle, sir, which smells.*"

Amid the universal laughter he retired to another car, but not until he had shot back, "Madam, as long as I live I'll *never forget the smell from that bottle.*"

The Medical College of the State of South Carolina.

Dr. T. Gaillard Thomas, No. 600 Madison Avenue, New York, has sent the following communication to the newspapers:

Through a letter just received from Professor J. Ford Prioleau, Dean of the Faculty of the Medical College of the State of South Carolina, located in Charleston, I have, as an alumnus of that institution and a native of Charleston, been warmly appealed to in its behalf, and requested to solicit aid from the medical men of our country for the restoration of its shattered buildings and ruined appliances for instruction.

"I have been requested by the faculty of this college," says Dr. Prioleau, "to write to you of the desperate condition of its buildings, and to ask you to endeavor to obtain for us some means of replacing the institution. Unfortunately the property will not bear any security, and the friends who so willingly would help us are as much wrecked as ourselves . . . It is with regret that we are forced to make this appeal."

The winter session of this venerable and eminent institution, which numbers among its teachers in the past Samuel Henry Dickson, Louis Agassiz, and Eli Geddings, and among those of the present some of the most worthy men in our profession, should begin in one month. If aid be not rendered it, quickly as well as generously, its doors must be closed for the coming season.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE THREE WEEKS ENDED SEPTEMBER 18, 1886.

Austin, H. W., surgeon. Granted leave of absence for thirty days, September 16, 1886.

Goldsborough, C. B., surgeon. Promoted and appointed surgeon from October 1, 1886, September 9, 1886.

Yemans, H. W., passed assistant surgeon. Granted leave of absence for ten days, September 16, 1886.

Bevan, A. D., passed assistant surgeon. Promoted and appointed passed assistant surgeon from September 1, 1886, September 7, 1886. Granted leave of absence for thirty days, September 7, 1886.

Glennan, A. H., passed assistant surgeon. Promoted and appointed passed assistant surgeon from September 1, 1886, September 7, 1886.

Norman, Seaton, assistant surgeon. To proceed to Vineyard Haven, Mass., for temporary duty, September 9, 1886.

The Preparation of Skeletons.

An account has recently been published of a novel industry, to which a large manufactory in the suburbs of Paris is devoted, viz., the preparation of skeletons for the market. The proprietor contracts for a supply of corpses from all the dissecting-rooms and hospitals in the city, and the raw material on its delivery is boiled for days in a cauldron. The grease which rises to the surface is skimmed and sold; the bones are carefully cleaned and bleached in the sun, and finally assorted and converted into articulated skeletons. The preparation of frogs, lizards, and various reptiles, occupies a separate department. The comparative cheapness and abundance of the skeleton supply from Vienna since the Russo-Turkish war has somewhat depressed the trade; but really good osteological preparations, as might be expected, always command a good price. For what purpose the grease which is sold is used is not stated, though we hope the silence is not to be regarded as significant.

Mistakes in Prognosis.

In the discussion at the recent meeting of the British Medical Association at Brighton on the duration of life with heart disease, Dr. Bristowe made some very excellent and apposite observations on this subject. "It is," he said, "quite early enough, in my opinion, for a man to know that he has heart disease when he begins to feel the effects of it;" and with this sententious remark most practitioners will agree. Incalculable harm has often been done by the abrupt announcement that a patient has cancer, or that another has heart disease; and the evil is aggravated by the fact that, as in all human affairs, the diagnosis may be wrong, or the prognosis may not be realized. Sir Andrew Clark told a very amusing, but instructive anecdote of his having been called to see a gentleman suffering from bronchitis, who, fifty years before, had been precipitately superannuated on full salary, on the announcement by the medical officer to an insurance company that he was the victim of an incurable form of heart disease, and would probably not live more than six months.

The Only Arabic Medical Paper.

Egypt boasts of only one medical journal, *El Shifaa* (The Cure), which was started last February, and so far has been a great success. It is published monthly, the price being thirty cents, at the offices of a native scientific paper, and is edited by a Syrian in Cairo—Dr. Shemeil—and Dr. Milton. At its start the sanitary department offered to buy 120 copies and distribute them among their officials; but as it was at once found that the native doctors brought its circulation up to 400, the offer was declined. It already pays its way, and will, it is to be hoped, be of incalculable benefit to provincial doctors possessing a modern medical literature. The chief contributors are natives of Egypt and Syria, and Dr. Milton, besides publishing many hospital cases, is now writing on the Treatment of Wounds. Dr. Kartulis, of Alexandria, has recently contributed a paper on the Giant Amœbæ, which he maintains are specific of dysentery.

She Would Not Have a Male Doctor.

The *Med. Age* says that a Parisian journal tells a story of a young married woman who was about to become a mother, but who objected to being attended by the family physician because of his sex, and insisted upon having a midwife. Not wishing to expose her to any of the dangers of the ignorance of this class, the physician conceived the idea of having a young beardless friend, who was a competent obstetrician, dress in female attire and personate a midwife. The ruse worked to the entire satisfaction of all concerned but the doctor, who was put to a severe trial by all the female members of the family, who insisted on his examining sundry little tremors and blemishes on various parts of the body which they would not expose to the gaze of a male doctor. The wounded modesty of the young M. D. was, however, healed by a plaster in the shape of a 500-franc note.

A Suit to Recover for Services.

The *N. Y. Med. Jour.* tells us that an action is now pending in which a New York physician seeks to recover a balance of between three and four hundred dollars, alleged to be due him on a contract to treat a patient for a year, supplying the necessary apparatus, for the sum of seven hundred dollars. Half this amount was paid at the outset, but subsequently the patient's father dismissed the physician and refused to pay the balance. He was, of course, at perfect liberty to decline the doctor's further services at any time, but we fail to see on what ground he should be excused from carrying out the pecuniary part of the agreement. He maintains, to be sure, that the doctor's treatment of his daughter was injurious; but that is a stock answer in cases of the sort, and it is gratifying to learn that in this instance the court granted a motion that the answer should be made more definite.

Remarkable Poisoning Cases.

A serious and remarkable case of poisoning is reported in the British medical papers as having occurred at a wedding breakfast in Carlisle. In all, nineteen persons partook of the meal. Four only escaped unharmed. One person, the bride herself, died on the fifth day. The dishes were all prepared by a professional cook the previous day, and kept in a dry cold cellar. No peculiarity of taste was noticed, except a little bitterness of some of the jelly. The symptoms were much like those of cholera. They were peculiar in appearing late. The breakfast was at noon; some of the persons were taken ill at 8 p. m., others at midnight, some the following day, and one on the second day. The source of the poisoning is as yet wholly unknown. Metallic poisons seem to have been excluded, and some ptomaine has been suspected.

The Homœopathic Treatment of Profanity.

"Another mental condition characterizing anacardium is a propensity to swear. (*Hahnemann Monthly.*) Now, do not suppose that I recommend anacardium for the cure of profanity when it exists as a result of low morals; far from it. When, however, the propensity to swear comes as a result of mental disease, anacardium may do noble work. I once treated a minister who exhibited a remarkable *penchant* for profanity. Try as hard as he would, he could not help it. Anacardium made a complete cure in his case. Another remedy producing a disposition to swear, is *nitric acid;* but I have never seen it do any good in these cases, excepting after the abuse of mercury."

The Whipping-Post Demoralizing in its Effects on the Community.

The whipping-post is at work in Delaware, and the Medical Jurisprudence Society of Philadelphia has been discussing the propriety of adopting it in Pennsylvania. The general sentiment, however, was opposed to it. Quite recently twelve convicts at New Castle, Delaware, were punished with the lash. The infliction of the punishment was public, and was the cause of considerable merriment to the spectators. It is not difficult to believe that the moral effect upon a community is bad, if such spectacles as the whipping of convicts are allowed to be witnessed by the public.

An Extra Coroner Wanted.

A correspondent of the *Medical Brief* states that Mr. Savory, President of the Royal College of Surgeons, was recently going round his wards at St. Bartholomew's Hospital, when he came to a case of hernia just operated upon. Turning to one of the students following him, he asked: "You have passed, have you not?" An affirmative answer was returned. "What is a good thing after an operation for hernia?" "A dose of opium." "How much would you give?" "Ten grains." "How would you give it?" "The liquid extract." "How much of it would you require to give your ten grains of opium?" "Half a drachm." "They will not be long before they require an extra coroner in the district where you settle down," was his comment.

The Editor of "The Lancet's" Confession of Faith.

Some time before his death the late Dr. James G. Wakley made a special request that the following confession of faith should be introduced into any notice of his life which might appear in the pages of the *Lancet:* "Feeling my deep responsibility to God for the position in which, in His providence, He has placed me, I desire to testify to the comfort derived during my sickness from a lively faith in our Lord Jesus Christ, and that I die in the sure hope of a glorious resurrection."

Reception to Dr. E. O. Shakespeare.

Dr. E. O. Shakespeare, who has passed the last year in Europe and Asia as the special representative of the United States to inquire into all the phenomena connected with the propagation, spread, and prophylaxis of cholera, returned to his home, in this city, on the 19th of last month. On Wednesday evening last he was tendered a reception at the Hotel Bellevue, at which there were present the most prominent members of the profession in this city. Dr. Shakespeare has brought home with him some very valuable data in reference to cholera, and his report will be read with very great interest.

A Large Vesical Calculus.

Mr. Thomas Smith reports, in the *Lancet* of August 7, 1886, the removal of a stone weighing 24½ ounces from the bladder. The stone was ovoid in shape, and measured 13 inches in its largest circumference and 9½ in its smallest. On section it was found to be dense in structure and regularly laminated, and to consist of phosphates externally, with a large oxalate nucleus. The patient was a soldier, forty-three years of age. The calculus was removed entire by the suprapubic operation, and the patient recovered completely.

High Death-rate in Kansas City.

During the week ending August 21, the death-rate of Kansas City reached the very alarming figure of 31 per 1,000 inhabitants. This is by far the highest death-rate ever known in Kansas City, the average for the past fifteen years having been about 15 per 1,000. The city is said to be in a very unsanitary condition, and the high mortality has been attributed to that cause.

The National Board of Health.

The Washington correspondent of the *N. Y. Med. Jour.* says that the National Board Health, having failed to receive any appropriation from Congress, have given up their

quarters on G street, and taken down their sign. Except the secretary, Mr. Dunwoody, none of the members of the board have been on duty for many months, and no meeting has taken place. There has, however, been little necessity for a meeting, as the powers of the board over quarantine matters long since expired by statutory limitation.

The Health of Chicago.

According to the "Condensed Statement of Mortality," for August, the whole number of deaths during the month was 1,352, including 1 from carbuncle, 201 from cholera infantum, 6 from cholera morbus, 18 from croup, 27 from diarrhœa, 11 from dysentery, 74 from diphtheria, 38 from entero-colitis, 5 from erysipelas, 8 from cerebro-spinal fever, 1 from intermittent fever, 2 from remittent fever, 21 from scarlet fever, 57 from typhoid fever, 13 from typho-malarial fever, 16 from measles, 2 from pyæmia, 5 from septicæmia, and 15 from whooping-cough.

Late Childbearing.

Dr. A. O. Banes writes in the *Medical Brief* that there is an aged and respectable couple residing in St. Joseph, Mo., the husband seventy-one and the wife sixty-five. This enterprising woman gave birth to a fine, healthy boy, much to the surprise of their kind neighbors and to themselves, as she thought an ovarian tumor was developing.

Lunacy Commission.

At the meeting of the Philadelphia County Medical Society on September 8, Drs. Mills, French, and Henry were appointed a committee to visit all asylums for the insane in the county of Philadelphia, in accodance with the request of the State Commission in Lunacy.

Condemnation of a Midwife.

In Altenburg, recently, a midwife was sentenced to imprisonment for two years, because she advised the parents of an infant suffering from ophthalmia not to seek medical advice. The only treatment consisted in local applications of chamomile tea, and the child lost one eye in consequence.

A French Verdict.

A coroner's inquest was held a short time ago on the body of a woman who, it appeared, had been suffering from heart disease, and this bringing on a fit of despondency she had taken a dose of Paris green. The coroner's jury found that the woman had died of "heart disease accelerated by partaking of a dose of Paris green."

Personal.

—Medical Director A. L. Gihon, the accomplished president of the Section in Medical Climatology and Demography of the International Medical Congress, has been ordered to Mare Island, California.

Items.

—The title of Doctor was invented in the twelfth century, at the first establishment of the universities. William Gordenia was the first person upon whom the title of Doctor of Medicine was bestowed. He received it from the college at Asti, in 1329.

—The fifteenth annual meeting of the French Association for the Advancement of Science took place on August 17th, at Nancy. M. Frudel, Professor in the Paris Faculty of Sciences, and Member of the Institute, was elected president. Some interesting papers were read.

—The Georgetown Medical Faculty have their new college building in Washington nearly completed, and expect to have it ready for lectures October 1. The introductory lecture this year will be delivered by Dr. John B. Hamilton, the professor of surgery.

—The Australian intoxicant, pituri (Duboisia hypwoodi) is said to be found only in one stretch of Australia, thirty miles in length. It is chewed into a pulp, and ashes added to it, after which it is rechewed several times. It is then ready for use as an article of commerce between the Australian tribes. On these it seems to have the same effect as alcohol.

—At a recent meeting of the Conseil d'Hygiène, M. Dujardin-Beaumetz drew attention to the subject of the removal of *débris* from butcher's shops, tripe-shops, and pork-butchers. He urged that the Prefecture of the Police should be called upon to strictly enforce the regulations issued on September 1, 1883. The carts used to remove these remains leave on their track a most offensive smell. Dr. Dujardin-Beaumetz suggests that these vessels should be disinfected daily before being used. The Conseil has named a commission to decide on the best disinfectant to be used for this purpose.

Pallas Syringe." The most useful instrument for Vaginal Medication and Irrigation.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

W. H. WALMSLEY & CO.,

SUCCESSORS TO R. & J. BECK,

Manufacturing Opticians,

No. 1016 Chestnut St., Philadelphia, Pa.

Microscopes,

Microscope Accessories,

Mounting Materials,

Dissecting Instruments,

Prepared Objects,

And every article pertaining to the Practical Work of the Microscopist.

Our New Lens Front, or Magnifying **Clinical Thermometers,** with **Indestructible Register** and **Ineffaceable Scale,** are the best and cheapest in use. Thermometers, Barometers, and Urinometers of all kinds and of the best makes.

Condensed and Illustrated Price List of 32 pages mailed to any address, **Free.** Full Catalogues of 172 pages for Fifteen Cents in Stamps. Mention this Journal.

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter. INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,

36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superintendent and his assistant Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

CRITICAL REMARKS ON FRACTURE OF THE OS FEMORIS.

BY EZRA MICHENER, M. D.,

Of Toughkenamon, Chester Co., Pa.

Apologetical.—While I highly esteem the urbanity and professional attainments of my good friend Prof. Ashhurst, I must also accept him as the authorized *exponent* of the present teachings and methods of my honored *alma mater*. And his expositions sometimes cause *regrets*, which I feel it to be my duty to express.

I well remember when, seventy years ago, it was considered a *Quiz Club feat* to lay down *Prof. Physick's* dressings for fracture of the thigh with neatness and accuracy ready for the patient, when the fracture had been reduced. And the inquiry comes up, What progress have we made in these *three-quarters of a century?* We naturally look to our *exponent* for the answer. Well, we have knocked the *Physick block* off Desault's *long splint*, and have laid the *foot-tie* aside. We have *renounced* the time-honored *sine qua non*, the *reduction* of the fracture and *restoration* of the shortened limb; and we have substituted the "*American Treatment*," the *pulley weight* of a *hod of bricks*, more or less, to do—WHAT? To restore the *length* and *service* of the limb, with an *acknowledgment* that it is not capable of doing so.

My Dear Doctor: I am aware that my earnest expressions in regard to this grave inquiry have been accepted as the effect of undue excitement, or as the flickerings of expiring reason in an old man. No! *my dear doctor!* I am indeed an old man, having braved the storms of *ninety-two winters;* but THOSE were not the senile sentiments of *yesterday*. They were the warm and vivid inspirations of *seventy years* ago. And the observations and experience of a long life has not abated their *freshness* or *intensity*. I may have reached the *goal* of human effort, but not that of a *desire* to alleviate the sufferings of poor humanity; though the *appeal* may seem to come back from the *portals* of another world.

I shall speak of fracture of the *shaft* of the os femoris as a *typical* lesion; leaving the surgeon to modify his procedure to meet any *complication* that may occur.

It must be remembered that the treatment of fractures is *mechanical*, and success will very much depend on the *skill* with which it is applied. The best means may fail in the hands of a careless or *clumsy* operator. They necessarily involve suffering and inconvenience to the patients, and it is the *sacred duty* of the surgeon to alleviate the one and ward off the others to the extent of his power.

Reference may be made to MED. AND SURG. REPORTER:

1881, January 8, On Fracture of Os Femoris.—*Michener.*

1881, November 19, How Bones Break.—*Michener.*

1882, February 4, Clinic on Fractures.—*Ashhurst.*

1882, December 31, Review of Clinic.—*Michener.*

1883, January 20, Another Clinic on Fractures.—*Ashhurst.*

1884, March 15, The Fracture Apparatus.—*Michener.*

The *sequence* as well as the *scrip*, seems to have a significance in this connection.

The inquiry resolves itself into four problems:

1. How bones break.
2. How to diagnose.
3. How to reduce; and,
4. How to treat—fractures.

I. How Bones Break.

Fractures are said to be either transverse or oblique, the latter being much the most frequent. This is *literally* true. But a long experience, sustained by the *artificial* fracture of *hundreds* of the long bones of animals, assures me that the obliquity seldom exceeds *forty-five degrees;* often much less.

I have learned from the same sources that the cylindrical bones *generally*, if they do not *always*, break in a *dentated* or toothed form, capable of *interlocking* and holding the fragments in position. And also, that this interlocking may readily be effected at the angle of obliquity, above named, or even a higher one. I would therefore, as a *practical guide* rather than a *literal truth*, consider all fractures *transversal*, so long as the fragments will *abut*, and *interlock*, and *hold* themselves together, aided by the *tonicity* of the femoral muscles.

My note of November 20, 1881, was written at the suggestion of mutual friends, and presented the views noticed above, with the conclusions to which they seemed to lead.

The response: "November 24, 1881. No doubt most fractures are, at first, serrated, and this serration may for a time keep the fragments together. Yet, on the conversion of the bone into granulation tissue—which precedes union—those serrations sometimes disappear, and hence consecutive shortening is very common. I cannot recall more than a single instance in which I have succeeded in curing fractured thigh without shortening."*

This reply was not satisfactory.

A graduate of the University of Pennsylvania, with the honored impress of a *Physick* and a *Wistar*, who ventured to think and to act upon his own responsibilities, after having treated a series of those fractures, as they presented during a period of more than half a century, in accordance with *views* and *methods* in a measure peculiar to himself, and with a success believed to have been *unknown*, and after having given them to the public, asked the *Professor of Clinical Surgery*, in his *alma mater*, to investigate them. The reply was courteous, but curt:

"I cannot recall more than a single instance in which I succeeded in curing a fracture of the thigh without shortening."

And in a clinic a few days later he enforced the same sentiment:

"In adults, a certain amount of shortening is, I believe, unavoidable."

Is this, then, the *ultimum thule*, beyond which inquiry must not—can not go? Our boasted *science* is hardly prepared to tolerate such a degree of *transcendentalism*, from whatever source it may emanate.

The professor, in his clinic, illustrates this softening by an *extraordinary* case. He says:

"I remember a case in the Pennsylvania Hospital who had made a *good recovery* from fracture of the thigh, and was allowed to go about at the end of six weeks. There was, at that time, one-fourth or *one-half of an inch* shortening. After two or three days there was found *two inches* of shortening. At this time the callus uniting the bone is soft, and the pressure from walking readily causes consecutive shortening." (The italics are mine.)

I say *extra*-ordinary—so soft, that an *inch and a half* of the thigh bone should be thus *squashed out*, like so much putty, and the man still able to walk on with such a condition of the limb!!! Is there not a mistake here?

As I had just reported more than a *decade* of typical cases, from infancy to old age, without *shortening*, or a *limper*, and that, too, without *mechanical extension*, I could only reconcile the conflicting results by referring them to the *antipodal* methods we had employed—the one treating the *man* without treating the *fracture;* the other treating the *fracture* without treating the *man*.

II. The Diagnosis.

I have little to offer, except it be a caution not to harass the sufferer with needless pain. It is enough for us to know that a fracture exists. An old physician had just dressed a fracture of a humerus for a young lady, when a former student came in. The dressings were *kindly* removed to allow him to diagnose the case anew, to the great annoyance and suffering of the patient. It was a long-remembered cruelty. Where there has not been displacement and shortening, a sharp, deep-seated pain from the slightest sudden motion will generally tell both the existence and the location of the lesion.

III. The Reduction.

Here we must *part hands*, as the clinic

*I understand this expression to mean an *appreciable shortening, with a limp*—not what a medical friend has called "an inappreciable shortening, without limping."

appears to entirely ignore the *reduction* of fractures; does not even name the procedure.

The bones are so many *stretchers*, to keep the muscles in a healthy tension, ready for immediate action. When the stretcher is broken, their innate tonicity causes them to *retract*. Hence the usual shortening in this lesion. And this increases and becomes more *inveterate* the longer it remains displaced.

The remarkable manner in which bones break seems to indicate a wise provision for their more easy restoration. It is strange that the profession should neglect to avail themselves of so valuable an assistant.

It has also been found that retracted muscles, or other tissues, while they strongly *resist* any sudden movement, will passively *yield* to slow and gentle *suasion* without causing pain.

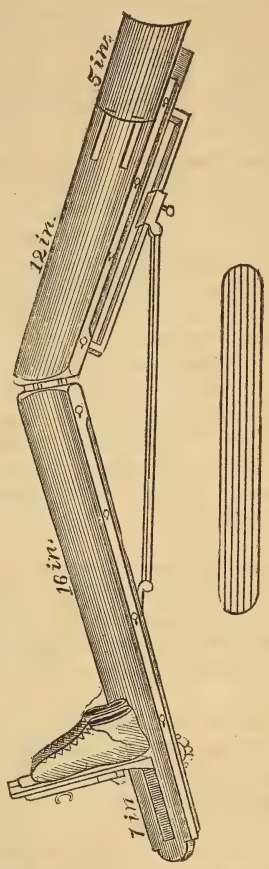
Before proceeding to reduce the fracture it may be well to have the dressings ready for immediate use. If difficulty is apprehended, place a long band under the shoulders, bring the ends over the axillæ in front and fasten them to the bedstead, for *counter-extension*, and provide a trustworthy *assistant* for a pull—a long pull—and, may be, for a strong pull; for it must not be forgotten that in most cases a slow, cautious change can be effected almost without pain. *The tensile force* should be in an *inverse ratio* to the *complaints of the patient;* no matter how much time may be consumed. The most refractory muscles will eventually yield.

While the extension is being thus cautiously made, the surgeon must carefully manipulate the limb and watch the descent of the lower fragment until it gets clear of its fellow, when it will usually fall into position; and as the dentures drop together, they may not be easily displaced. The reduction may be tactile, or even audible, to the operator.

The tension may now be relaxed, as slowly as it had been made, to ascertain whether the bone will again serve as a *stretcher* for the limb. If it fails, further trial should be made. Finally, it may be necessary to dress the fracture while the full extension is kept up; and, perhaps, it should be continued for some time after. I have not seen such a case. When the fracture has been fairly adjusted, the femoral muscles are an excellent adjunct to hold them together.

IV. The Dressing, etc.

Sixty-five years ago (1820), I constructed an apparatus for fracture of the thigh in order to obviate defects in the methods then in use. It was partly on the plan of the *Amesbury apparatus.* Its use, for that long period, and in a variety of cases, from infancy to old age, has proved highly satisfactory. The figure explains itself.



APPARATUS FOR FRACTURE OF THE OS FEMORIS.

The apparatus is seen to consist of a concave *bed splint* cut into two at the knee and united by *hinges*, with a sliding brace and binding tap screw to fix it at any desired angle. At the upper end is a broad brass *sliding plate*, with binding screws to adapt the length of the splint to the limb. Its edges are provided with *buttons* for the reception of four pairs of strong leather *straps* with buckles. Three *minor splints*, made of thin strips of wood, glued on muslin, answering to the length and thickness of the thigh, a strong *bandage of straps*, and *pads* for the splints, complete the essential dressings.

For the reception of the foot, and to adapt the apparatus to injuries of the leg, the lower section of the splint carries a *sliding standard* with a laced *shoe*, in which the foot may rest. It is also provided with side splints,

straps, etc. (not shown), for treatment of injuries below the knee.

In the case of children, I have always used an *improvised angular splint*, made on the occasion, by nailing two pieces of shingle on an angular block. The application and after-management were the same, and have been satisfactory.

The application is easy. If it was not done before reduction, remove the foot-gear, set the splint to a proper angle, say one hundred and twenty degrees, lay on the pad, and apply it accurately to the sound limb. The minor splints should also be trimmed to fit the thigh, from its top to the condyles and the patella, but never to *rest upon them.*

Now, lay down the bandage upon the pad and place the injured limb conformably on it. Apply the bandage tight; lay on the small splints with thin pads, and buckle the straps tightly over them. This completes the dressing proper of the fracture. The thigh was *broken*, and we have *dressed* the thigh.

Incidentally, the leg hangs over the lower plane. It needs a stocking. The foot-gear may be replaced and the foot be allowed to rest in the shoe, or on a cushion, to avoid the pain, too often produced, by pressure on the heel.

After a *rest*, and needed *refreshments*, revise every part of the appliances to know that there is *equable pressure*, and nothing to gall or produce irritation.

Remarks.—1. I studiously leave the *hip* and *knee* free to move that they may respond to any reflex motion of the patient instead of allowing it to fall on the *fractured joint.*

2. I have never used any form of *mechanical extension*, unless the angular splint be so considered.

3. I have not had either shortening or a limper.

Of the *softening and consecutive shortening* of fractured bones it may hardly become me to speak, for in the cases referred to it would seem that the *method pursued* had prevented either the *softening* or the resultant *shortening.* So far as my experience goes, I can hardly recognize it as *pertinent to good surgery.* It has presented to my mind, and I am willing to suggest whether it may not be *caused*, when it does occur, by the frequent disturbance of the fracture from insecure dressings—a form of *bone inflammation.* Two cases in which there could have been no mistakes go to sustain this view.

Case.—M. W., a child of seven summers, had her leg caught and dragged under a log, on the highway. The soft tissues of the upper anterior and inner tibial regions were entirely torn away, both bones broken, the leg doubled back upon the thigh, with the fragments all protruding more than an inch. After cutting away more than an inch of the upper tibia, which was denuded of its periosteum and left without any possible covering, the limb was placed on an angular splint, the nicely dentated ends of the fibula were held in the fingers and carefully interlocked, and supported by a light outside splint. Thus this young and broken *fibula* was made an efficient *stretcher*, and preserved the entire length of the limb during the long period of restoration of the *tibia.* There was no squashing out of *granulation tissue* here, for there was no shortening nor semblance of a limp.*

Case. Myself the sufferer. Some five years away, I fell with the right upper humerus across the sharp angle of a curb. The fracture click was unmistakable, and I immediately passed my hand over the *clavicle*, *acromion*, and *humerus*, without detecting a fracture. It soon became manifest in the latter, but was so near the joint that efficient dressings could not be applied. An axillary pad, with shoulder-strap to support and bind the arm to the side was applied, but was unsatisfactory, and permitted frequent disturbance of the fracture. I was not aware that the lesion had ever been much displaced. Union progressed slowly. But what was my surprise when putting on my coat to find the right sleeve apparently an inch longer than its fellow! *Ergo*, the injured arm was an inch shorter than it had hitherto been. I state the facts, others may apply them.

Resumé.

What John and Jonas say contrariwise.

John.—I had laid a good while, and there was much shortening, and it required a good while to restore it; but it was done so cautiously as scarcely to give me any pain, and there was no shortening afterward. The bone made all the *extension* required.

Jonas.—My bone was never *set.* I, as I then thought, had happily escaped a painful operation, with the promise that the after-treatment would do all that.

My *American patriotism* had all been knocked out by the fall, but it returned amazingly, as I was assured that I should have the "American treatment." I didn't then *know* what that was.

*As this case was somewhat remarkable and is made to carry an unusual weight of testimony, I am free to state that she is now the wife of Goodwin Chalfant, near Unionville, in this county, and will verify this statement.

John.—My limb was placed on a close-fitting, curved, angular splint, with the knee gently flexed—a *Scultett's bandage*, and *three minor splints*, extending from the top of the thigh to the condyles—*but not over them*—when buckled tightly around the limb, constituted the *entire fracture dressing*. A stocking, and other comforts for the leg and foot were only incidental.

Jonas.—I was dressed with two splints—an outer and inner one. The first, "simply a long piece of board," extending from the *axilla* to below the foot; the other from the *groin* below the foot. The outer splint rests upon the projecting point, of the *hip* and external *condyle;* the inner is held off by the *big end* of the thigh and inner *condyle*. Neither can give much *lateral support* to the fracture. To do this the interspaces were filled with *bags of bran*, which could hardly be expected to do better. I was finally *pinioned* down to this "long board" by five strong bands, and a *weight-extension of one brick* hung to the foot. (American!!)

John.—I laid *conformably* on a comfortable bed, with *bolster and pillows*, can be raised or even set up a little, and be laid off to refresh the bed. I suffered no pain, except from too long-continued pressure on the *heel*.

Jonas.—I laid *unconformably* on an uncomfortable bed. I soon learned the significance of the "American treatment," and pronounced it *a tricuspid horror*, and withal a *failure*. *Its first cusp is* to be *pinioned down* on one's back to a long board from head to foot—a sort of *straight waistcoat*, worthy of the Inquisition. *Its second cusp is* the *weight extension* of bricks, increasing from day to day up to a hod-full, more or less, as the necessity of the case, or the whim of the doctor, may require. "Some surgeons use from twenty to thirty, and even forty pounds."

The third cusp is the *counter-extension*, made by elevating the foot of the bed three notches higher than the head, with the promise of another notch for every additional brick. Nevertheless, "as far as my experience goes, shortening occurs after all fractures in adults."

The two *forces—muscular contraction* and *gravitation*—one vital, the other mechanical, are *discordant*. They do not and cannot be made to *coördinate*.

John.—After six weeks the tight dressings were laid aside for lighter and looser ones. The *femoral muscles*—not the *doctor*—did not allow me to walk. They had been too tightly bound to resume their functions for some time. I used a crutch for a week or two.

Jonas.—At the end of six weeks my dressings were removed for lighter ones, but I was not permitted to walk on the injured limb.

John.—After eight weeks I was able to walk freely, without any *appreciable shortening*. But I was obliged to go out without the privilege of a *limper's diploma*, or a bill of *indictment for bad surgery*.

Jonas.—Eight weeks ago "I did not suppose much shortening, as extension had been made for forty-eight hours," but on measurement it was still found to be one inch. But "this afternoon we shall probably add *another brick*, and in the course of a *week*, a third." This was all done according to *Gunter*. But here I am with a limb still *one inch short*, and a *limper* for life. In return, I hold a *bona fide limper's diploma*, and a chance to *claim five thousand dollars* damage for *bad surgery*.

CONCLUSION.

My views may prove erroneous; they are certainly immature and not fully developed. The methods derived from them will doubtless admit of successful modifications. All I desire is, that they may be tried upon their own *intrinsic merits*, and be aceepted or rejected, according to their *value*, regardless of the *bossism of rival schools* and the *assumed authority of high positions*.

Unhappily, *great men* make *great mistakes*. *Sanguiphobia* is not the only error taught in the schools, which, when innocently and confidingly carried home by their thousands of medical students, tend largely *to people the tenement houses of the dead*.

ON SOME FACTS CONNECTED WITH THE ETIOLOGY OF TYPHOID FEVER.

BY R. W. HUTCHESON, M. D., M. R. C. S., ENG., ETC.,

Of Queen's County, N. Y.

Very much has been accomplished of late in extending our knowledge of the etiology and natural history of many diseases; so much so in fact that the science of medicine is making vast strides toward the time when it may be classed among the exact sciences. But there is much to be accomplished yet before that desirable era is reached; nevertheless the discoveries that have been made in our own times, and the skill and increased interest that have been lavished on very recent investigations, make us sanguine in our expectations that the near future is pregnant with results growing out of these investigations and discoveries; in other words, that

we are on the threshold of an important era in the history of the science of medicine. Would that we could say the same of the *art* of medicine! The fact is, the treatment of diseases at the present time is in a terribly muddled state, as any one who has been practicing medicine for twenty-five or thirty years must admit after reading some of the latest works on the practice of medicine. Not so, however, is the practice of surgery. The recent development of the germ theory has put surgery on a pinnacle of fame which few of us ever dreamed it would have attained in our day. And to the indefatigable exertions of professor Lister, of King's College, London, much of this success is no doubt due, for with his antiseptic dressings he has clearly demonstrated that much of our former ill success in surgery was due to the free access and rapid increase of germs in wounds; but by avoiding these and establishing proper drainage, wounds can now be rendered comparatively harmless, and healing by the first intention easily attained.

While these grand discoveries are being recorded they should stimulate each worker in the vast field of medicine and surgery to add his mite to the material that is wanted to make the sciences exact. City physicians and surgeons no doubt are doing Herculean work in investigating diseases; but they are not in a position to find out everything. There are many facts connected with medicine and surgery that the country doctor can discover, which do not come under the cognizance of the city practitioner. Facts, I say, are constantly occurring in the practice of country practitioners which if duly recorded would help to set at rest many of the uncertainties connected with the sciences of both medicine and surgery.

To illustrate my remarks let me take a disease, say typhoid fever. Now repeated observations have taught us how that disease is communicated from person to person when it has once started in a community. But whether typhoid fever originates *de novo*, and if so, how, are open questions; at least recent writers on medicine, ignoring the opinion of Murchison and other competent observers, tell us so. Now I ask, Could not the combined experience of the medical profession of the country solve that? Having had quite a number of cases of typhoid fever under my observation during the last twenty-five years, I have very naturally obtained some practical information from them, and a part of this relates to its etiology. I would, therefore, say that from my experience typhoid fever does originate *de novo*, and that the cause is the ingestion of decomposed animal tissues under certain conditions, and among these tissues I should mention dead toads, rats, snakes, etc. Not only have I had frequent proofs of this in my own practice, but I have known it to occur in the practice of other physicians. The mere presence of dead toads in a well is not the only requisite to generate typhoid fever; they should remain in it long enough to become thoroughly decomposed, so as to impart a decided odor and taste to the water. In the instances that occurred in my practice, the wells were completely enclosed, so as to exclude the light, and only a very limited amount of stagnant air reached the water. It would indeed be a very interesting discovery if the bacillus typhosus could be demonstrated in these putrid walls; and, if they are the real exciting cause of the fever, they surely must be present in such instances in enormous quantities.

The following are some of the cases that I remember to have occurred in my practice where typhoid fever originated *de novo*.

1. A few years ago I was called to attend three children, living with their mother in a neighboring village. They had been complaining for several days, and were then ill with fever. There had been no cases of typhoid fever in the neighborhood for years, and the children had not been from their home for months previous to their illness. No one from any other part of the country had visited them. Every circumstance in fact incontestably proved that the disease could not have been communicated to them from any one. When a glass of water, drawn from the well from which they obtained their supply, was handed to me, I immediately detected an odor in it. "What is the matter with the water?" I inquired. "We don't know, doctor; the water has smelt like that for some time." "Don't drink another drop of it until the well has been cleaned," I replied. "The children are suffering from typhoid fever, and the cause of the fever you will no doubt find in the well." On the following day the top of the well was removed, and the *fons et origo* of the mischief soon came into view. Several dead toads, decomposed to a pulp, were found floating on the surface of the water. The fever in these cases ran the usual course, and the children under my care recovered. But an elder brother, living in the city, visited the house during their illness. He contracted the fever, and died at his lodgings away from home.

2. A year or so subsequent to this, I was summoned to attend another case of typhoid

fever. It was that of a farmer, aged fifty, residing with his wife and two children, who were at the time quite well. Before I arrived, these people had themselves detected that there was something wrong with the well-water, and had ceased to drink it. When the well was opened the surface of the water was found covered with the decomposed flesh of dead toads.

When informed that the illness was typhoid fever, the other members of the family were very much afraid of catching it. I answered them that the disease was not communicated from person to person like measles and scarlet fever, but was contracted in other ways—notably, through drinking water; that if they were careful in disinfecting and burying the excreta, and refrained from drinking their well-water, they would not take the disease. This allayed their fears for a time; but in about two weeks, down came the mother with the fever, and in a few days more the two children were also taken down with it. This, in their estimation, rather tended to upset my knowledge of the contagiousness of typhoid fever, and I had to set to work to discover how the disease originated in these latter cases. The family had ceased drinking the well-water, and had disinfected and buried all of the excreta. But there was another channel by which the fever might be communicated, of which they little dreamed, and that was through the milk. "Do you boil your milk before you use it?" I inquired. "No, we do not." "Where do you water your cows?" "From the well." "From the tainted well?" "Yes; we use the well-water for all other purposes, except drinking." This inquiry threw a flood of light on the subject; the cows drank the tainted water, the milk-pails and other utensils were washed with it, and those who drank the milk thus contaminated contracted the fever. This confirms a fact that was first shown by Ballard in 1871, and has been frequently mentioned of late by several writers, and is about the clearest case of the kind that has come under my own observation.

Soon after the fever had attacked the children, the friends employed a nurse to assist in taking care of them. She also, at first, was afraid of catching the disease. I assured her that if she would follow my instructions, and not eat or drink anything from the house where the sick were, she need have no fears of contracting it. She followed my advice and escaped.

3. In 1883 I remember attending another case of typhoid fever in which the disease no doubt originated in the house where the patient resided. But in this instance the water was obtained from a driven well, which, as a rule, is less liable to contamination than the water from an open one. The house was built on a low plot of ground, and about four feet of pipe readily reached the water. There was a water-closet in the house, and the pipe leading from it ran under the kitchen, right by the pump, which had been driven but a few feet in the ground. Just where they met there was a leakage, and for months fecal matter had been allowed to escape and penetrate the soil, and thus reach the drinking water. The family resided in an isolated part of the country, and there was no other case of typhoid fever in the neighborhood at the time. The disease was of a severe type, but the patient finally made a good recovery. The drainage pipe was properly fixed, disinfectants were freely used, and no other case of the fever occurred in the family.

4. In the last part of August, 1885, a party of young folk, numbering some fifteen, started out to spend the day on the banks of a creek, near East Rockaway. They carried no water with them, but relied on procuring a supply from a sunken barrel near the creek that had been used for that purpose for a number of years. On this occasion it was noticed that the water smelled and tasted badly, so much so that some of the party refused to drink it. Exactly one week from the day of the picnic most of those who had drunk the water, some nine in number, were stricken down abruptly with typhoid fever. I regret very much that I did not have an opportunity of examining the barrel with its contents immediately after the picnic, as I am now left in doubt as to the cause of the decomposition in the water. Shortly after the outbreak of the fever, some person, fearing that others might drink the water, pulled up the barrel and destroyed the well. But from a number of reasons I can positively say that there was no possibility of the water being contaminated with the fecal matter of a patient suffering from typhoid fever, which is the recognized way of communicating the disease; and if the germs of the fever did not originate *de novo* in the well water, I ask the question, Where did they come from?

I might mention that the disease in these cases pursued the usual course of typhoid fever, some of the patients being ill for four or five weeks. There were several cases of relapse, and one of these died. The patients were treated differently. Quinine was ad-

ministered to some of them, both in small and large doses, but it had no effect in shortening the duration of the fever, thus clearly proving that the disease was not malaria.

TREATMENT OF PRURITUS PUDENDI.

BY E. S. M'KEE, M. D.,

Of Cincinnati.

In a paper read before the Cincinnati Academy of Medicine, September 20, 1886, on Pruritus Pudendi, the author discussed that interesting section, the treatment, as follows:

First, we should ascertain the cause of the disease to treat it intelligently. We should treat the constitutional diseases as the origin of the trouble. Next, we should treat the morbid phenomena, the pruritus. Remove the cause, and the pruritus will disappear of itself. The parts should be washed twice a day with castile soap and water. The diet should be vegetable, and regular action of the bowels maintained. As a general rule stimulants should be disallowed.

In this troublesome trouble, for we can hardly call it a disease, we need all the remedies we can find, hence I give all I know.

4	per cent.	solution of	boracic acid.
3-10	"	"	carbolic acid.
2-5	"	"	argenti nitratis.
0.5	"	"	bichloride of mercury.
25-50	"	"	sulphurous acid.
6	"	"	sodii biborat.

Ointments of tar, boracic acid, camphor, or iodoform, mixtures of camphor and chloral, infusions of tobacco, 20 per cent. solution of chloroform in almond oil.

Treatment with the bichloride should be preceded by a removal of the mucus with warm water, and then dry with soft linen. Pass a sponge moistened with the solution rapidly over the affected part. This leaves a smarting, burning sensation, which is alleviated by a few minutes' washing with cold water. Subsequent applications become less and less painful.

M. Dubois recommends in the rebellious cases that the entire surface of the vulva be cauterized with a solid stick of the nitrate of silver. The great objection to this is that it is extremely painful, and the alleviation produced by it is almost always temporary.

Meigs recommends:

℞. Borax, ℥ij.
Morph. sulph., gr. ivss.
Aquæ rosæ dest., ℥viij.

M. S.—Apply three times a day to the affected part with a sponge or soft piece of linen. Take care to wash well the parts beforehand with soap and warm water, and dry them well afterward. A compress dipped in the oil of sweet almonds and laid in the commissure of the vagina, is recommended.

When the trouble is general, temporary relief may be obtained by placing the woman in a prolonged soda bath, and subsequently rubbing the entire surface with vaseline.

Pruritus which has extended upon the distended abdominal walls is well treated with,

℞. Lin. saponis comp., ℥v.
Chloroformi, ℥j.
S.—Apply locally.

If the itching comes from an ulcerated cervix, or more properly from the irritating discharge proceeding from it, apply nitrate of silver, and introduce a tampon of tannoglycerine.

Pruritus from breeding pediculi is well treated by mild mercurial ointments. Staves-acre answers well. A plasma formed of flour of sulphur and water, saline purgatives, as Pullna or Friedichshall water. Vichy baths, or even bathing with cold or tepid water, constitute the best palliatives. Salines and colchicum may be indicated, also bromide of potassium. A weak solution of Goulard's lotion, or a lotion composed of

℞. Liq. morphiæ hydrochlorate, ℥j.
Acid Hydrocyanic, ℥iss.
Aquæ, ℥vj.
M. S.—Use as a lotion.

Pledgets soaked in the following and placed in the vagina have been found useful:

℞. Acidi sulphuric,
Sodii biborate,
Acidi sulphurici,
Glycerini, āā ℥ij.
M.—Insert at bed time and withdraw in the morning.

Iodoform may be dusted over the parts. The following has often given relief:

℞. Chloroformi, ℥ij.
Ol. amygdal., ℥ij.
M. S.—Apply externally.

Morphia and chloral internally may be found necessary to obtain relief at night. Hildebrant has found the tinct. cannabis indicæ, x.-xx. gtt., to be of even more benefit than these.

There is no end to remedies; the trouble is to get the right one.

℞. Extract opii, gr. v.
Plumbi acet., gr. x.
Acidi hydrocyanici, dil., ℥j.
Aquæ, ad., ℥j.
M. S.—Apply on lint to the vulva.

Or,

℞. Liq. plumbi subacetat., ℥j.
Acid hydrocyanici, dil., ℥j.
Aquæ, ad. Oj.

℞. Acidi tannici, ℥ij.
Extracti belladonnæ, gr. x.
Butyr. cacao., ℥v.
M.—Div. in suppos. No. xx.
S.—Insert one in the vagina night and morning.

℞. Sodii biborat., ℥ij.
Morph. sulph., gr. vj.
Aquæ rosæ, ℥viij.
M. S.—Apply to the vulva on lint.

Trousseau recommends—

℞. Potassii carbonat., ℥ij.
Aquæ, ℥iv.
M. S.—Lotio.

℞. Hydrargyri chloridi mite, ℥j.
Adipis, ʒj.
M. Ft. ungt. S.—Apply locally.

A solution of nitrate of silver (i–℥j.) applied to the neck and cervical canal, so far as accessible, will often remove the pruritus even when due to pregnancy. If due to vesicular eruptions on the genitals this application should be made to the affected part.

Fox recommends the following:

℞. Sodii hyposulphitis, ℥iv.
Glycerini, ℥ij.
Aquæ dest., ad. ℥vj.
M. S.—Lotio.

℞. Hydrargyri bichloridi, gr. j.
Acidi hydrocyanici dil., ℥j.
Emulsion of almonds, ℥vj.

℞. Acid hydrocyanici dil., ℥ss.
Infus. marshmallow, ℥v.
M. S.—Apply twice daily.

℞. Sodii biborat, ℥j.
Acid hydrocianici dil., ℥ij.
Aquæ rosæ, ℥viij.
M. S.—Use in the pruritus of old people.

℞. Ammoniæ acet., ℥j.
Acid hydrocianici dil., ℥iss.
Infs. tobacco, ℥viij.
M. S.—Apply twice daiiy.

McCall Anderson recommends:

℞. Potassii cyanidi, gr. vj.
Pulv. cocci, gr. j.
Ungt. aquæ rosæ, ℥j.
M. S.—Use as ointment.

Guerneau de Mussey recommends the following:

℞. Infs. marshmallow, 1 litre.
Cherry laurel water, 50.00.
Sodii. sub borat., 10.00.

He then prescribes an ointment to be used night and morning as follows:

℞. Glycerole of starch, 20 00.
Pot. bromid.,
Bismuthi subnit., āā 1.00.
Hydrarg. chlor. mite., 0.40.
Ext. belladonnæ, 0.20.

De Savignac uses the above lotion, and then dusts the surface with the following powder:

℞. Pulv. lycopodii, 30.00.
Bismuthi subnitratis, 19.00.
Bellad. rad., 2.00.

Dr. Martineau recommends an ointment of cocaine 1 in 10.

It is claimed by German writers that this pruritus is localized on a certain small area of the mucous membrane, and that by the removal of this part by the knife we remove the cause. This, I think, would have no effect on a case dependent upon the pregnant state, a discharge, or the condition of the urine.

EDITORIAL DEPARTMENT.

PERISCOPE.

Paralysis Depending upon Idea.

Dr. C. W. Suckling thus writes in the *Lancet:*

In the *Birmingham Medical Review* for June, 1885, I published an account of a boy who had suffered from paralysis of one leg for two years, and whom I was able to cure immediately after making the diagnosis of paralysis depending upon idea. Since then I have met with three other cases, two of which were men. In one case there was complete anæsthesia of the hand; in another hemi-analgesia with localized and severe headache. In the four cases I have now seen, an accident occasioning slight injury was the exciting cause in each. All four cases were rapidly cured. Dr. Russell Reynolds, I believe, first described paralysis depending upon imagination. There is no malingering in these cases, but the patients are firmly convinced that they are suffering from paralysis. If the confidence of the patient be gained, an immediate recovery follows when he is told that he will be well immediately, the idea being got rid of. In making the diagnosis it is important to bear in mind the two classes of people in whom functional nervous disorders are met with—the neurotic and the hysterical—the features of which have been so graphically described by Dr. Clifford Allbutt in the Gulstonian

Lectures for 1884. It is the neurotic that is apt to be affected by these paralyses depending upon idea, and it is these cases that are instantly cured when the diagnosis is made. The hysterical patient is cured with difficulty and frequently relapses; the neurotic does not relapse. The neurotic individual is vivacious, good-tempered, unselfish, intelligent, active, and industrious, anxious to be cured, and grateful for recovery. The hysterical individual is listless, apathetic, lazy, selfish, with characteristic expression, not usually anxious to get well, or thankful for recovery. The following is the fourth of these cases of paralysis depending upon idea that I have met with during the last twelve months.

Sarah F., a widow, aged forty-six, was sent to the Queen's Hospital, to be admitted under my care, by Dr. Middleton, of Harborne, on the 15th of March last, and was discharged well on March 28. She has led a very industrious life, having supported her five children by needle-work since her husband's death ten years ago. On October 9, 1885, she tumbled downstairs, falling down twenty-one steps on to her back. She was much hurt and "dazed" and very much frightened, thinking every bone in her body was broken. She walked about after the accident for a day or two, but suffered from pains in the back, down the legs, and round the body; these pains were intermittent, very severe, and lasted altogether three weeks. Two days after the accident she took to her bed, and a day or two later found that she was paralyzed in both her legs, and had lost all feeling in them. Since the accident she had suffered from constant headache and backache. Upon examining her, I found that she had a little power over the legs, but very little. Slight ankle clonus could be elicited on the left side. The plantar and abdominal reflexes were lost, but the knee-jerk was well-marked. There was complete analgesia and thermal anæsthesia in both legs up to the knees. She was unable to localize tactile sensations below the knees, the anæsthesia not being complete. When touched with a sharp-pointed instrument she said she felt as if she were being pushed. Muscular sense was unaffected. There was superficial tenderness over the lower dorsal spines, but no pain on firm pressure or on percussion, and no irregularity of the spine. The bladder and rectum were unaffected, and I was informed by Dr. Middleton that she never lost control over the bladder, nor had any sign of bed-sore during her illness. There was no œdema of the legs, no alteration of the temperature, and no change in in the color or aspect of the skin or nails. In fact, there were absolutely no trophic changes whatever. The response of the muscles to faradization of their nerves was normal, but there was considerable electrical anæsthesia. In summing up the symptoms present, I of course observed their incongruity if we supposed the case to be one of myelitis, or, in fact, as due to any organic lesion. If the anæsthesia were due to actual lesion of the grey matter, how could the bladder and rectum escape? How was it that there was no sign of bed-sore, no œdema, or other atrophic change, such as muscular wasting? I diagnosed the case immediately as being purely functional, and, the woman being of the neurotic type, as paraplegia depending upon idea. I at once acted upon this diagnosis, and told the patient that I should give her the battery, which I said would at once remove the loss of sensation and enable her to move her legs as well as she ever did. She was delighted to hear this, and after a minute's faradization sensation was completely restored, and she had full command over her legs. I then told her that on my next visit I should expect to see her walking about the ward, for I was sure that she would be able to do so. I instructed Dr. Whittendale, my house-physician, to see that she got up after I left, and to apply the faradic current whenever she displayed any hesitancy. On my next visit, two days later, I found her up and able to walk and run about the ward perfectly well. She was quite delighted at her recovery, and had been most industrious with her needle since getting up. She expressed deep gratitude, and hoped to be able to repay our kindness. I may add that I saw my patient on the 14th of the present month (September), and she was remaining quite well.

How was the cure effected in this case? Undoubtedly, I think, it was by the mental state of faith or expectation, or both, on the patient's part. She fully believed what I told her, and thus I was able to remove the idea she had that she was paralyzed. The essential thing, then, in these cases, is to make a correct diagnosis, and then the patients can safely and with success be told that they will quickly recover. Now, had this been a hysterical woman, I should, in all probability, have failed to cure her, or, at any rate, the cure would have been more tedious. I recently had a woman under my care suffering from locomotor ataxy with hysterical anæsthesia. For two years I did all I could to cure the anæsthesia, and failed; but when she left the infirmary she applied leeches to

her legs and returned with the anæsthesia gone. Isolation, so useful in hysterical cases, is not needed in these.

In the same ward with my case of ideal paralysis there was a young woman suffering from hysterical neuralgia, and the contrast between the two patients was very marked. The hysterical woman was listless and apathetic, did not manifest any desire to be cured, and would scarcely allow that she was any better than when admitted. When told that she was well enough to go back to her duties as a teacher, she seemed disappointed, and said that she did not intend to begin work again for some months. The neurotic woman, on the contrary, wanted to leave the hospital immediately she could walk. The hysterical woman was observed to be always sitting opposite the neurotic woman, contemplating her, with her hands idly folded in her lap, watching the other busily working.

Such cases as these illustrate the enormous influence of the mind over the body. It is with these cases that the so-called faith-healers work pretended miracles. What an opportunity for a faith-healer my case would have afforded! Just as the mind has an enormous influence in causing disorders of sensation, of motion, and also of the organic functions, so, also, its influence can be used as a practical remedy in disease. As Dr. Wilks has well observed, "the practice of medicine is not only one of physic, but of psychology also."

Is Cirrhosis of the Liver Curable?

The *Medical News* says that this question has been discussed recently at La Société Médicale des Hôpitaux, according to the *Gazette Hebdomadaire*, Nos. 31 and 34, and answered affirmatively by several members, who quoted cases which seemed to bear out the view that the disease may be arrested or even cured. The diagnosis of cirrhosis is rarely reached until the onset of symptoms of obstructed portal circulation, although before this stage the condition may be reasonably suspected. The cases of cure are those in which the ascitic fluid has not reaccumulated after treatment, or, after a hæmatemesis, the symptoms have been relieved and the patient has had years of tolerable, or even good, health. Most physicians have met with such instances among their alcoholic patients.

In the discussion referred to, eight cases were reported by four or five members, and from the details we can reasonably infer that the ascites depended upon the cirrhosis. But we must be careful not to confound the relief of a symptom with the cure of the disease. The post-mortem room affords examples of advanced cirrhosis in persons dying of intercurrent affections in whom there has never been any history of hepatic trouble, and on the other hand, the most extensive dropsy may exist with a very moderate grade of interstitial change. We must look beyond the liver for an explanation of these facts. In the first place, unquestionably, we must take into account the collateral circulation carried on by the diaphragmatic, œsophageal, and lumbar plexuses, the hemorrhoidal anastomoses, and the veins of the round ligament; if enormously enlarged, these may partially, or even fully, compensate for the narrowed portal channels, as in the rare instances of obliteration of the vena portæ. The degree to which this collateral circulation is established varies extremely in different cases, and is a very important factor in the duration of life in this disease. It will be found that the very instances in which advanced cirrhosis has been accidentally discovered post-mortem are those in which there are numerous supplementary blood-channels.

The two most striking symptoms of cirrhosis are ascites and hæmatemesis, in both of which the venous radicles of the portal vein are directly concerned. We are apt to consider them as immediate results of the heightened blood pressure, due to the narrowing and obliteration of the interlobular vessels; but Cohnheim's experiments indicate that this alone cannot induce either diapedesis or serous exudation. The condition of the vessels themselves must be taken into account, and in altered states of their walls we must seek an explanation of the sudden and profuse hæmatemesis, or the rapid dropsy. The abruptness with which one or other of these symptoms may supervene, as possibly the very first manifestation of the disease, points plainly to disturbances in the radicles of the portal veins, and not in the central hepatic branches, which in the indurated organ must be much less subject to variations in calibre.

Heretofore we have been in the dark as to the nature of these peripheral changes, but Dieulafoy has determined, in certain cases, the existence of a subacute peritonitis, and in four instances periphlebitis of the walls of the rootlets of the portal veins. These lesions have not been fully described, but their existence throws light on the origin of the dropsy and the hemorrhage, and they possibly furnish the additional factor which, as Cohnheim insists, is needed to permit

transudation of blood corpuscles or plasma under heightened blood pressure. The dropsy may be due to transitory and remediable causes, anæmia for example, and does not necessarily indicate that the contraction of the portal canals has reached a high grade. These are points which must be considered in discussing the curability of cirrhosis, and, as we remarked, the relief of a symptom may not mean the removal of the disease.

We probably have not any remedies at our command which are capable of curing a cirrhotic liver. The nature of the tissue change is such as almost to preclude the possibility of restoration, but in the early stage many practitioners place great reliance upon drugs, particularly the salts of gold, phosphate of sodium, chloride of ammonium, and, as recommended by Dujardin-Beaumetz, hippurate of lime. Unfortunately, the diagnosis in the cases in which these remedies have been reported to be successful is often a matter of doubt, and we very strongly suspect that when a case of cirrhosis presents features clearly enough marked for detection, the interstitial hepatitis is probably beyond arrest, as it is certainly past cure.

Fatal Case of Chorea Associated with Rheumatism and Cardiac Disease.

Dr. Martin Oxley thus writes in the *Lancet:*

The following interesting case has recently come under my notice:

Harriet B., aged ten years, had measles, scarlet fever, and whooping-cough before she was three years old. At the age of five she was in the Infirmary for Children suffering from rheumatism and chorea. She was admitted into the infirmary on the 21st of April of this year. Her mother stated that three weeks previously she began to suffer from rheumatic pains in her joints, and that one week before she was brought to the infirmary chorea set in. On admission, the patient complained of pain in the right knee and right wrist. She was also suffering from a well-marked attack of chorea, most marked on the right side. The choreic movements were more violent during the night, when awake, than in the daytime. The heart's apex beat in the fourth and fifth interspaces, internal to the nipple line. There was slight epigastric pulsation. A rough systolic thrill could be felt over the apex. There was a loud grating systolic murmur, heard most distinctly over the axilla. There was no œdema or albuminuria. A few days after admission she had clonic twitching of the right side of the face, accompanied by incoördinated movements (described by the house-surgeon as being like an infant's convulsion). The patient improved considerably, and on May 25 she was sent to our convalescent home at Waterloo. She remained there for three weeks, and seemed to be improving in health and benefiting by the sea air. On her return (June 14) to the infirmary, it was noticed that there was much greater impulse over the cardiac region, and that the apex was now outside the nipple line. The chorea had disappeared, and she was allowed to be up and about the ward. A few days after her return she was noticed to have a slight rise of temperature at night (101°), and she was ordered back to bed. On July 2 the heart symptoms became much more marked, and her face and feet became œdematous. From this time she became rapidly worse, and died on the morning of July 11.

Post-mortem Examination.—There was slight œdema of the legs and eyelids. Heart very much enlarged, displacing the lungs, especially the left, and extending, partially covered by the thin edge of the lung, about half an inch to the right of the sternum and to the lower border of the second left rib. Pericardium: A patch of thick, firm, white adhesion, about the size of a sixpence, situated over the right ventricle near its apex, attached the two layers of pericardium; there were no other signs of pericarditis. On the surface of the aortic, mitral, and tricuspid valves, minute vegetations about the size of a pin's head were to be seen grouped in clusters. The aortic and mitral valves were both incompetent. The lungs were congested and œdematous all over; the left pleura was slightly adherent at the back. The liver was most typical nutmeg, and a large and apparently recent infarct was found on section.

Remarks.—This case, taken with others which have been reported, helps to strengthen the opinion held by many, that rheumatism and heart disease are responsible for chorea; and the fact that in chorea we frequently cannot find evidence of heart disease is no proof that there is no valvular disease. This was very well illustrated in a case which I brought before the members of the British Medical Association at their meeting in Liverpool in 1883. It just happened that many of my colleagues were examining cases in order to supply information to the Collective Investigation Committee, and a patient who was under my care at that time was frequently examined with the view of detecting

heart disease. No cardiac bruit could be detected, and there was no apparent hypertrophy; yet, notwithstanding, after death, which occurred unexpectedly during the chorea from exhaustion, vegetations about the size of pin's heads were found to fringe the aortic and mitral valves. In both these instances the vegetations were very small, and were very readily detached from the valves. In two other fatal cases of chorea which I have had under my care, the patients being of the ages of seven and eleven respectively, one had vegetations on the aortic and mitral valves, while the other had well-marked pericarditis and nodular rheumatism as described by Drs. Barlow and Warner.

Piperine in Intermittent Fever.

Dr. C. S. Taylor thus writes in the *Brit. Med. Jour.:*

As many cases of intermittent fever seem to resist the use of quinine, and all the other remedies in ordinary use, the following cases, which fell under my observation, will, I trust, exemplify piperine as an excellent addition to our knowledge of the treatment of this disease.

Case 1. M. J., aged 18, had suffered periodically, upwards of two years, with intermittent fever. It appeared that she had taken sulphate of quinine in great quantities, and in large doses, with the effect of only subduing the disease for a short time. She was sent abroad for a change of climate, and every other means had been used to cure the disease, without success.

Treatment.—She was directed to begin as soon as perspiration commenced, without regard to the heat of the skin, or quickness of the pulse, 3 grains of piperine every hour, until 18 grains had been taken; and on the following day, when intermission was complete, the same quantity every three hours. This has, in every case, succeeded in checking the paroxysm, and as soon as that is accomplished for some days, the following pills, taken in the morning, noon, and evening, will be found beneficial:

℞.	Pilulæ hydrarg.,	gr. j.
	Piperinæ,	gr. ij.
	Quinæ sulph.,	gr. iij.
	Syrupi, q. s.	

Should the second paroxysm be escaped, the following pill should be taken every third hour:

℞.	Piperinæ,	gr. v.
	Mucil. gum. acaciæ, q. s.	

It is now upwards of three years since the patient was treated, and she has continued free from the malady.

Case 2. Mrs. C., aged 34, had had several severe paroxysms of tertiary intermittent fever, but very irregular in its attacks. Infusion of cinchona, as well as sulphate of quinine, had been freely taken, but to no advantage. On April 15, while taking a cold bath, she was seized with ague. At 7 a. m. I found her shivering severely. I ordered warm drinks to be given frequently. At 12 o'clock, cold shivering continued, and the symptoms were alarming; the pulse was scarcely felt. The skin was cold, universally clammy, and unpleasant to the touch. The lips were of a slate-color. The countenance was contracted, the eyes sunken, and the patient evinced marks of great agitation and alarm.

Treatment.—Hot flannels were applied over the chest and abdomen; the legs and feet were rolled up in hot cloths, and stone vessels, filled with hot water, were constantly kept under her arms, and along the inside of the thighs and legs; and warm brandy toddy was given frequently in small quantities. At 4 p. m., finding the reaction could not be brought on, five grains of piperine were given. This was with great difficulty swallowed; it was, therefore, washed down with an ounce of brandy, in half a tumbler of champagne. Afterwards, full doses of the aromatic spirit of ammonia were ordered to be taken every third hour, and the champagne to be continued. At 6 p. m. reaction commenced, and, as the heat increased, the hot applications and stimulants were suspended. At 8 p. m. heat was general, and in proportion to the cold stage. On the following morning, the sweating stage commenced; and, as soon as it was general, five-grain pills of piperine were ordered to be taken every second hour, and continued for four days. On physical examination, the liver and spleen were found to be enlarged and hard, yet free from pain when pressed. The following pills were prescribed, and the patient was ordered to take one every two hours:

℞.	Piperinæ,	gr. xxxvj.
	Pilul. hydrargyri,	gr. xij.
	To be made into twelve pills.	

In case the bowels were not open, a wineglassful of the following mixture was to be taken when required:

℞.	Sulph. magnesiæ,	℥iss.
	Sulph. quiniæ,	℈ij.
	Acidi sulph. dil.,	℥ij.
	Aquæ puræ ad.,	℥xx.

It is now three months since she first had an attack of the disease. Health perfectly restored.

There are a great many patients having an objection to taking quinine in consequence of its affecting the head; but the piperine, although a powerful stimulant, carminative, and febrifuge, does not in the least degree, from personal observations, affect the sensorium.

Chancre of the Gum.

Dr. D. N. Kinsman thus writes in the *Cleveland Medical Gazette:*

The peculiar mode of infection in the following seems to justify its publication. While there is, of course, an element of doubt, such as must exist in all such cases, I feel sure its origin is such as I shall detail.

B. consulted me June 24 concerning a swelling of the cervical and sub-maxillary glands on the right side. They were large, hard, painless, and without the adhesions to the surrounding tissues usual in the ordinary cases of adenitis of their duration.

In seeking for a cause for their development I found an ulcer surrounding the right middle incisor, in the upper jaw. This ulcer had been under treatment by a dentist for several days, and by him was supposed to be due to an accumulation of "tartar," which had extended beneath the gum and caused the ulceration. It had been treated with iodine locally.

I told him the glandular swellings were due to the ulcer, and when it healed the swelling would disappear. He returned to the dentist for treatment for a few days. I saw him again July 1. There was no change in the aspect of the case, except the glandular swelling was increased, and the glands of the other side of the neck and those in the occipital region were also involved.

I found he had fever and headache, for which I gave quinine. July 3 he was worse and sent for me to see him at home. At this visit the case became clear, for the papular syphilide upon his face, chest, and arms left no possible doubt. He subsequently had nocturnal pains in the head and shins, and pharyngitis and patches upon the tongue. Under specific treatment he did well, and in five weeks the apparent manifestations had disappeared. Three years ago this man was treated for supposed syphilis. This diagnosis seems to have rested upon the occurrence of a sore upon the penis and a consecutive suppurating bubo. He had none of the secondary accidents of syphilis.

For some time the origin of this chancre was a mystery. Finally, I learned that B. was having sexual relations with a young woman who was living at home, and that they had continued for more than a year. In the early part of May, or last of April, this young woman, who till then had been free from all sores, had a fissure on her lip, which was cauterized with a crayon of nitrate of silver. This fissure took on the appearance of a broad-based sore, so the young man says, and for some time refused to heal. Finally, the glands in her neck enlarged. She had an eruption, and, upon consulting a physician, the case was diagnosticated syphilis, and accordingly treated, when her symptoms subsided.

B. supposed that he had been poisoned when kissing her while her lip was sore, and I am led to believe, from all I can learn, this woman was contaminated by the crayon of silver, which may have been soiled by contact with a chancre on some one else. Such modes of infection are common enough. This case, as well as others, teaches us we cannot be too careful to protect others from contamination by soiled instruments which have been used about syphilitics.

Circumcision Under Cocaine—Improved Operation.

Dr. E. R. Palmer, Professor of Physiology in the University of Louisville, writes to the *Med. Record* that, desiring to perform circumcision under cocaine, he determined to use Corning's method of sequestration.

"The patient, a young man, twenty years old, with a complete congenital phimosis, was seated in a chair, and the penis was seized by my assistant and drawn upon firmly. A Martin bandage, seven-eighths of an inch wide and a yard and a half long, was next applied, the first turn being made behind the scrotum to prevent slipping, and the bandage being then wound tightly back and forth from the symphysis pubis to the corona and back again. An ordinary hypodermatic syringe was next filled with a six per cent. solution of cocaine, and the needle, directed toward the extremity of the penis, was passed at four different points through the skin over the glans, a fourth of the contents of the syringe being discharged each time into the subcutaneous tissue. No attempt was made to introduce the drug from the mucous surface. In about three minutes I began adjusting a Rogers clamp, occupying as many more minutes in getting it placed to suit me and screwed down. The prepuce was removed with one stroke of a pair of long curved scissors, and the clamp removed. The dorsal artery was found not

bleeding; the frænum was not cut. The mucous membrane was split up, and some eighteen sutures leisurely introduced. The bandage was now removed, and, contrary to expectation, no hemorrhage ensued. Less than a drachm of blood was lost during the entire operation. The wound was dressed loosely with absorbent cotton wet with equal parts of listerine and water. Not a twinge of pain was felt after the last needle puncture had been made. The young man, of nervous temperament, was at first quite pale, but later assisted in the stitching, and as he washed his hands after the operation remarked that his penis still felt dead. The wound healed in forty-eight hours by first intention.

"The advantages of the bandage are several: It wholly controls bleeding, it localizes the action of the cocaine, and it increases the facility with which the penis can be handled during the operation. The reverse direction for application, that is, from behind forward, will be found the best, because the easiest, and fully effectual."

Dr. Palmer adds that he performed the operation a second time in the same manner, with equally good results as regards anæsthesia. But the continuous suture was used, and although perfect coaptation was accomplished, some trouble was experienced later from swelling and from syphilitic induration of the parts. It was attempted to remove the suture, but this was found impossible, and the writer thinks it would have been better had interrupted sutures been employed. The case is now doing quite well, however, and the result will be good.

Note on a Rare Dislocation of the Elbow-Joint.

Dr. C. George Battiscombe thus writes in the *Lancet:*

On April 9th I was called to see a gentleman who had met with an accident while hunting. I found him lying in a field, and was told that his horse, after jumping a fence with a long drop, had fallen over backwards upon his right arm and leg. He complained of great pain in the elbow-joint on the slightest movement. It was very much altered in shape, and evidently severely injured. I secured the arm in a sling, and had him removed to the Cottage Hospital (Chiselhurst, Sidcup, and Cray Valley), which was close by.

On his arrival at the hospital I examined the arm, and found it in the following condition: The forearm was fixed at rather more than a right angle to the arm; all power of natural movement of the elbow-joint was lost; and any attempt at forcible movement caused great pain. The hand was partially pronated, but on turning it pronation and supination could be readily performed. The elbow-jointa ppeared too wide from within outwards and from before backwards; it presented two prominences below, an inner and outer, and one above the latter, which projected backwards and was continuous with the forearm. The inner angle of the joint was too high, so that the arm appeared to be shortened. There being no amount of swelling, the following points could be clearly made out. The ulna and olecranon were missing from their natural position in relation to the humerus, the two condyles of which could be distinctly felt with the notch between them. The ulna and olecranon were resting fully half an inch above the external condyle of the humerus, the elbow projecting about an inch beyond the latter. The radius could be felt above, with its head resting against the outer border of the humerus. It was not separated from the ulna, and rotated readily on pronating and supinating the hand.

I put the patient under chloroform, and carefully examined for any fracture. I could find none whatever, and concluded that it was a case of complete dislocation outwards of both bones of the forearm. I then proceeded to reduce the dislocation. Grasping the forearm with one hand, and the elbow with the fingers of the other, I pulled it steadily downwards, endeavoring to get the olecranon over the external condyle. It took some minutes to do this, and required a good deal of force. Then, holding the olecranon below the condyle with the left hand, I seized the forearm lower down and used it as a lever, and while forcibly extending the forearm I rotated it outwards. On continuing the extension, the olecranon suddenly slipped into its natural position. The joint immediately answered to all its proper movements, but when left alone tended slightly to return. I fixed it at a right angle on a posterior angular splint.

When I called in the evening the patient was free from pain, and complained only of a feeling of numbness in the arm and hand of the injured side. The next morning, when I arrived at the hospital, he had gone home; but I ascertained that, beyond the numbness and a little swelling, he was very comfortable. A week afterwards he was doing well, could move the joint pretty freely, and was free from pain.

Complete lateral dislocation of both the bones of the forearm is, I believe, extremely rare. I have seen no description of it, though it is mentioned in several surgical works.

Antipyrin as an Analgesic in Headache.

Dr. John Blake White, Physician to Charity Hospital, New York, sends the following to the *Medical Record:*

"The high road to truth is the knowledge of facts, and well is it for searchers after truth when facts can be ascertained and carefully recorded.

"Symptoms are the alphabet, cases the language, of disease, and that physician subserves his profession who carefully records his experience.

"During the past two years I have abundantly tested the therapeutic value of the drug known as antipyrin in various forms of headache. The prompt relief obtained through its use compels me to accord to it a high rank among our medical resources. I have already called attention (*Medical News*, July 10, 1886,) to the potent antipyretic power possessed by this remedy in the management of various forms of fever, and have observed that after its administration the urgent symptom of headache, so uniformly present in these cases, was soon controlled.

"Antipyrin undoubtedly possesses bradycrote properties in a high degree, as the pulse is notably softened and moderated in frequency soon after a proper dose of it has been taken. It produces some somatic change favorable to a reduction of the pulse in cases of fever, and so exerts a calming influence upon the vaso-motor system. The capillaries, through its agency, doubtless dilate, and local congestions are dissipated, as the relieved patient usually sinks into a refreshing repose soon after its exhibition. In the course of large experience with antipyrin I have found that, when administered in masterful doses, it not only promptly relieves the symptom of headache whenever present, whether resulting from disordered digestion, disturbance of the menstrual functions, loss of sleep, undue mental effort, or even that associated with dreaded uræmia, but also possesses reliable prophylactic virtues against recurrent attacks of cranial neuralgia. So confident am I of the power of this remedy to disappoint neuralgic headache when imminent, that I have instructed many patients, who are liable to such visitations, to keep in readiness and take a dose of antipyrin as soon as they have premonition of its recurrence, and all so far testify in favor of its efficacy.

"The value of this remedy in the above respect has not only been tested in my hospital and private practice, but I also record the fact it has proved successful in the hands of professional friends, upon whom I had urged its employment for the relief of neuralgic affections of the head and face. I have been singularly impressed with the promptness of relief which often followed the administration of even a single dose of fifteen grains of the antipyrin. The grateful relief from headache usually ensues within half an hour after the drug is taken. A sense of drowsiness ordinarily supervenes, followed by a brief but sufficient slumber, and the patient awakens quite relieved of this distressing symptom. I have never yet seen the sleep-disposing properties of antipyrin alluded to by any other observer, although this effect seldom fails to ensue when a full dose such as I have named has been taken."

Ergot in Labor.

Dr. J. W. Macfarlane thus writes in the *Med. Times:*

We notice in a number of journals of late that ergot is given a prominent place in the management of labor, some recommending it in the second stage, whilst others believe it to be indispensable to the proper management of the third. This journal of September 4 contains an article by Dr. Reichard endorsing it unequivocally in the third stage.

That ergot is a remedial agent of great virtue there is no question; that it should be given in every case of labor seems not only irrational, but harmful.

Labor is a physiological process, and where nature is capable of performing its functions properly it seems meddlesome, to say the least, for the *accoucheur* to give a dose of ergot when the after-birth is expelled and the uterus firmly contracted, under the impression that it will ward off septic trouble and what not.

It is questionable whether ergot should be given in the second stage of labor. One is probably debating whether to apply the forceps or not, and, to get out of the dilemma, or to be doing something, gives ergot. When I was a resident physician, hour-glass contractions of the uterus and retained placenta were not uncommon things under the use of ergot, and the consequent manipulation to remove the after-birth (which several times necessitated the introduction of the

hand) left the patients nervous, exhausted, and liable to hemorrhage.

When there is any difficulty in the third stage of labor, we use the Credé and Cazeaux methods combined. If there is a disposition for the uterus to relax after the removal of the after-birth, the patient is placed upon her back, and the fundus of the uterus is grasped with one hand, whilst two fingers of the other hand are introduced into the vagina. Under these circumstances the neck of the uterus is generally filled with a large clot. A little manipulation with the external hand and fingers within the vagina brings on firm contractions of the uterus, and the clots are forced out into the palmar surface of the hand, and thence into the bed.

In cases of post-partum hemorrhage we empty the cavity of the uterus that we may secure perfect contraction. Why not invite a relaxed uterus to contraction in the same manner, when we have the means so ready at our command?

We have never seen the above-named procedure fail to procure firm contraction, though we have, in certain cases where the patients were feeble, followed it up with ergot, to guard against any possible danger.

Lying-in women generally get along without a bad symptom. Why make them sick by the use of ergot?

The "Strangers' Cold."

Mr. R. Augustine Chudleigh writes to the *Brit. Med. Jour.:*

"Under its Maori name of murri-murri, I have been for eighteen years much interested in the St. Kilda cold, and everything connected with it. When Boswell and Johnson visited the Hebrides, in 1773, the disorder was evidently an article of popular belief, though the medical man himself had as little respect for the mysterious cold as for the Rev. Kenneth McAulay, who vouched for its existence. In *Tour to the Hebrides,* Boswell says, at page 126, that, from his conversation, Dr. Johnson was persuaded that McAulay was not capable of writing the book on St. Kilda which goes by his name. And, at page 343, he waxes merry over the idea of people catching cold merely because strangers came; for, says he, if one stranger gave them one cold, two would give them two colds, and a ship-load would kill them. He further adds that the evidence was not adequate to the improbability of the thing; and not till a physician should go to St. Kilda and report the fact would he believe in its existence. It appears from your journal that several physicians have visited St. Kilda since 1773, but they have not quite settled the question of *cnatan na gall* either way. May I, therefore, cite the case of the island of Wharekauri, one of the Chatham group, about 480 miles east of New Zealand, nearly at the antipodes of St. Kilda, where, under the name of murri-murri, an identical disorder, with a similar alleged origin, is now frequent. In its main features, murri-murri is indistinguishable from a severe influenza cold. Its invasion may occupy four hours; the patient remains 'intensely miserable' for about four days, when the disorder gradually dies away. No period of incubation precedes, and no permanent ill-effects are observed to follow. One attack does not preclude the recurrence, and European residents, as well as Maori and Muriori natives, are liable to the disorder. In order to be infected, a person need not know that a ship has come; indeed, the mere appearance of murri-murri is proof to the inhabitants—even at distant parts of the island, which is thirty miles long—that a ship is in port, insomuch that, on no other evidence, people have actually ridden off to Waitangi to fetch their letters. There is a hill whence one can see across the island into Waitangi Bay; and people are wont to climb this hill, and scan the bay for a ship, on no other evidence than the occurrence of murri-murri. It is very curious that the name of that hill is Mount Dieffenbach (see Mr. Dixon's letter, *Brit, Med. Jour.*, page 286, 'Darwin quotes *Dieffenbach,* etc.'), and that the ship that would have been descried thence would almost certainly have been the *St. Kilda,* which, for many years, did the trade of the islands. There may have been connection between St. Kilda and Wharekauri."

Effects of Syphilis in Pregnancy.

Dr. Louis Hirigoyen, who has published a series of articles in the *Journal de Médecine de Bordeaux* embodying the results of observations on the effect of syphilis upon the course of pregnancy, states that in the Bordeaux Maternity Charity, in which five-sixths of the cases are those of unmarried women, the syphilitic are 5 per cent. of the whole number. The author's observations go to confirm Fournier's dictum that "a syphilitic woman becoming pregnant is more likely to abort than a pregnant woman who becomes syphilitic." For example: Of eight women who had been syphilitic for more than a year, five aborted, one bore a child which died on the eighth day, and two bore living but puny

children. Of nine women who contracted syphilis within the first two months, six aborted at six months, and three at seven months, all of macerated children. Of three women who contracted syphilis during the third month of pregnancy, one miscarried at seven months of a macerated child, and two of a similar child at eight and eight months and a half respectively. So that in all the twelve cases where syphilis was contracted before the commencement of the fourth month miscarriage of a dead fœtus resulted, even in some cases in which anti-syphilitic treatment was diligently pursued, the only apparent effect produced being the retardation of the period of miscarriage. Syphilis occurring after the commencement of the fourth month proved less fatal, for of four cases which took place from the fourth to the sixth month, one brought forth a healthy child at eight months; the second, who was treated medicinally, went her full time, and was delivered of a healthy child; while the other two women were confined at seven and eight months respectively of puny children, which died shortly after birth. Where the infection was delayed till after the beginning of the seventh month, it proved still less fatal to the children. Thus, of seven cases of this kind four terminated in the delivery of apparently healthy children, and one more might have been born alive but for maternal dystocia. The bodies of the macerated children, as well as those which died after birth, were examined, and no definite syphilitic appearances could be discovered in the osseous or other parts. Of course, treatment was adopted where the woman was seen early enough, and in all cases stringent isolation and antiseptic precautions were enforced, with the result of the avoidance of all serious accidents.

A Study of the Cause and Treatment of Pelvic Hæmatoceles.

Before the Chicago Gynecological Society Dr. H. T. Byford cited the case of a non-suppurating, retro-uterine hæmatocele of six months' standing, which he evacuated *per vaginam* March 18, 1886, and then treated with antiseptic irrigations. She was up and about the house in eleven days. As the odor and discharge were still causing discomfort, the doctor, influenced by the advice of Apostoli and Doléris, curetted the cavity. He found no more blood or débris, but started up a mild attack of local peritonitis, which delayed instead of hastening the cure. The patient left the hospital in a little less than a month after the cessation of all discharge. A small lump of induration extending from the abscess opening to the right sacro-uterine ligament was all that was left of the tumor.

The following résumé of interesting points in the case is given:

1. The length of time from the occurrence of the hæmatocele to the time of operation, about six months.
2. The method of opening the cavity, viz., by first tearing the vaginal wall, and afterwards the sac wall.
3. The absence of fluid in the tumor.
4. The breaking up of the mass with the finger without an attempt at thorough curetting or removal of the entire contents.
5. The complete disintegration and discharge of all bloody substance in thirteen days.
6. The absence of high temperature—102° F. having never been reached.
7. The small amount of anodyne required—one dose (except the two doses to relieve the irritation from subsequent unnecessary curetting).
8. The toleration of strong antiseptic solutions. It was necessary to weaken them on account of their effect upon the vagina.
9. The absence of the usual amount of odor in such decomposing masses.
10. The large quantity of food taken throughout.
11. The absence of any kind of sickness from the beginning until the cavity was curetted.
12. The curetting of the cavity on the thirteenth day delayed her recovery, producing the only serious symptoms that were noticed.
13. Notwithstanding a set-back of ten days, caused by the curetting, she was well enough to go home inside of a month and dispense with treatment.
14. The attack came on after a miscarriage.

Emotional Icterus and Lichen.

So many cases of emotional icterus are on record that it is scarcely worth the while to enter into a statistical discussion to show the existence of such an affection. Dr. Negel, of Jassy, Roumania, reports, in *Progrès Médical*, of August 21, a "case of emotional icterus accompanied by a general eruption of lichen," which is sufficiently rare to give in detail. The patient was twenty-three years old, of robust constitution, with a tendency to obesity, and for some years subject to acne of the face and back, and there was

slight submaxillary engorgement. There was no hereditary taint in the patient.

In February, 1885, there was a herpetic eruption on his prepuce, which he himself treated with cauterizations of nitrate of silver, as a result of which there was an enormous ulcer and balano-posthitis. He then consulted a physician, who ordered emollient dressings, but the ulcer grew larger. To make a long story short, the physician finally told him that his penis would gangrene; but the patient showed so much alarm that Dr. Negel was consulted. When he arrived some time later, he found that the patient's urine was brown, and left a deposit in the *pot de chambre;* the fæcal matters were colorless, and there was slight constipation. This state lasted for two days, when the patient noticed that his saliva was bitter, and there was slight fever. There was now intense icterus, accompanied by an eruption of lichen, situated principally on the thorax (back and sides), abdomen, and face, the limbs and scrotum. It was of the simple variety, and presented a few vesicles here and there. The urine contained a great deal of bile pigment. An emeto-cathartic was given, and then saline purgatives, lemonade, bicarbonate of soda, and antiseptic dressings were applied to the ulcerated and swollen prepuce.

After ten days of treatment the ulceration and balanitis were almost cured, but the lichen persisted. The icterus had greatly diminished. After about three weeks the patient was practically well, but there was still some jaundice and lichen.

Diaphragmatic Hernia.

Il Bullettino della Reale Accademia Medica di Roma (May, 1886, p. 245) contains a description by Dr. Ferraresi of a diaphragmatic hernia revealed in the necropsy of a young man who had died with symptoms of intestinal strangulation. On surface inspection of the well-nourished body, it was noted that the abdomen was only slightly swollen; the left half of the thorax was broader and more prominent than the right, and the left intercostal spaces dilated. Percussion revealed an area of absolute dullness over the whole left chest, excepting the subclavicular triangle, which yielded tympanic resonance. On opening the abdominal cavity, the coils of small intestine, slightly reddened, presented small patches of fine basal injection. Carefully opening the thorax, the left pleural cavity was found filled with a bloody liquid, on giving exit to which the lung, compressed and driven upwards, became visible, the heart being displaced to the right. Besides liquid already referred to, the pleuritic cavity contained numerous coils of intestine enormously distended, of dull red color; the serous membrane was opaque, rough, and studded with numerous hemorrhagic spots. The stomach was displaced to the right, with the great curvature turned towards the abdominal wall. Holding aside the stomach and the small intestines, still retained in the abdomen, it was observed that the splenic angle of the colon and a good part of the jejunum passed into the pleural cavity through a hole in the left inferior half of the diaphragm at a point corresponding to the normal position of the heart's apex. The descending colon was much contracted. With great difficulty, and after repeated punctures, it became possible to reduce the coil of colon, a piece of omentum, and the displaced small intestine. The hole in the diaphragm was oval, rather more than in inch in diameter, surrounded by a strong, thick, fibrous ring. The gastro-colic omentum which followed the displaced coil was shortened, and adherent posteriorly to the margin of the fibrous ring.

Bacteriotherapy in Pulmonary Tuberculosis.

The plan of treating pulmonary phthisis by the inhalation of spray containing bacterium termo, the organism of putrefaction, has received a severe handling from some of the fellow-countrymen of its advocate, Prof. Cantani, of Naples. At a meeting of the Medico-Chirurgical Society of Pavia, held on March 20, Prof. Guiseppe Sormani read a paper on the subject. After criticising the principle from a theoretical point of view, he recorded three cases where the plan was carefully and rigorously carried out, and even for a longer time than had been recommended by Prof. Cantani. The results in these three cases were altogether negative. The conclusion was that bacteriotherapy was not a remedy, either rational or practical, against tuberculosis. Prof. Sormani thought, however, that the inhalation of the spray of fresh good meat-broth might act as a palliative against distressing cough, difficult expectoration, dyspnœa, and other symptoms. He advised, therefore, recourse to this means in suitable cases; without, however, for a moment thinking of first putting in the broth a bacterium which was certainly useless and might be noxious. Prof. Riva, in speaking on Sormani's paper, criticised the scientific basis of Cantani's method. The basis of the method was that there was a struggle for ex-

istence between the bacterium termo and the bacillus tuberculosis. The bacterium termo, however, subsisted only on dead substances; so that wherever one sent it, it would only take its nourishment from the excretions, or from mortified tissues, and would not attack the proliferating tissues of tubercle. The only result would consequently be the decomposition of the excretions, which, being in the neighborhood of a large absorbent surface, might be carried into the circulation, and might act hurtfully on the organism. In answer to questions touching Sormani's three cases, it was stated that in one case only was there a rise of temperature of some tenths of a degree. Whether the urea increased or not was not known.

Parenchymatous Injections of Quinine in Ague Cake.

Professor F. Fazio relates in the *Rivista Clinica e Therapeutica* for July, 1886, the case of a woman, thirty years of age, who had suffered from malarial fever, and who had also marked hypertrophy of the spleen. The tumor extended from behind the margin of the ribs to a line drawn on a level with the anterior superior spine of the ilium. It was determined to attempt a reduction in the size of the spleen by means of parenchymatous injections of quinine. The instrument used was the ordinary hypodermic syringe provided with a longer and thicker needle than usual. The bisulphate of quinine was employed, and thirty-two injections of each 4½ grains were made, care being taken to make the successive punctures at some distance from each other. The result of treatment was a reduction of over one inch in the length of the tumor. The injections were not followed by pain or by any other unpleasant symptoms. The experiment was interrupted by the departure of the patient from the hospital, but Dr. Fazio believed that the results obtained were sufficiently encouraging to warrant further trials of the method.

Scarlatina.

The *Birmingham Medical Review* contains a contribution to the pathological anatomy and histology of scarlatina by Dr. Crooke. It is remarkable that the mammilated appearance of the pyloric region of the stomach was very marked in a case that terminated fatally in twenty-six hours. Microscopical examination showed that this appearance was due to inflammatory hyperplasia of the adenoid tissue, which is normally present in the gastric mucous membrane of children and young adults, as Dr. Herbert Watney has demonstrated. At some places the hyperplasia is seen to be so considerable as to extend up to the surface of the mucous membrane, displacing in its extension the gastric tubules. Whilst able to corroborate the accuracy of the observations of Dr. S. Fenwick as to the presence of interstitial gastritis in scariatina, Dr. Crooke does not regard the interstitial change as evidence of a past morbid process. He believes that simple catarrhal gastritis occurs in a more or less marked degree in most cases of scarlatina, fatal during the febrile stage; but that in cases characterized by the exceptional severity of the gastric disturbance, where the interstitial changes are so pronounced as in three cases examined by him, the condition is usually, if not invariably, associated with a similar acute interstitial and follicular inflammation of the mucous membrane of the intestine, and is therefore to be regarded as part of an acute inflammatory attack, of which the chief stress falls on the adenoid tissue of the stomach and intestines.

Induction of Premature Labor.

Dr. T. Gaillard Thomas says: The method of inducing premature labor which I now invariably adopt is a very simple, and is at the same time a perfectly efficient one. The patient is placed across the bed, with the buttocks resting near the edge, and under is arranged a large piece of rubber or oil-cloth in such a way as to drain into a tub on the floor. In this tub we put one or two gallons of water at a temperature of ninety-eight degrees Fahrenheit. The operator stands between the thighs of the patient, whose knees should be properly supported, and employing a syringe with a long nozzle, which is carried up as far into the cervical canal as it will go, he keeps a stream directly against the membranes. In the course of ten minutes the os will be the size of a silver half dollar, and when dilation to this extent has been accomplished, he is to insert a gum catheter between the membranes and the uterine walls. The patient is then put to bed, rhythmical uterine contractions soon follow, and the labor is completed in a few hours.

—Free dispensaries are almost unknown in France, there being but three in Paris, according to the correspondent of the *Provincial Medical Journal.*

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

PHARYNGEAL CATARRH AND PEPSIN.

Dr. J. Fisher, of Berlin, had a patient suffering with chronic pharyngeal catarrh (*Berl. kl. Woch.* 49-86). Various local and internal remedies were tried in vain, until finally, the patient complaining of some transient gastric disturbance, caused by too luxurious a meal, the Doctor advised him to take five grains of Jensen's pepsin, which by the way is also recognized in Germany as the best pepsin in the market, immediately after each meal. The patient, who from the frequent medication had become averse to medicine, took the pepsin pure, ½ grain of aromatic powder being added to 5 grains of Jensen's pepsin simply to preserve the latter in its dry state. The effect was remarkable. Not only the stomach improved, but after three days' use the pharyngeal catarrh also showed decided amelioration. Dr. F. then administered the pepsin in still larger doses, ten grains each, and two weeks later the catarrh had disappeared. The same remedy was afterwards tried in four more cases and with the same result, but other pepsin preparations failed.

There is one symptom, that seems always to yield readily to Jensen's pepsin, viz., the peculiar dryness, of which patients suffering from chronic pharyngeal catarrh are so apt to complain. The remedy ought to be taken in its pure state, only a moderate dose of aromatic powder being added to keep it dry, and it should be allowed slowly to dissolve in the mouth.

There is a complaint intimately connected with the catarrh in question, viz., circular ulceration of the posterior nares. Patients suffering from this trouble usually have to hawk a great deal every morning, sometimes also in daytime, to their own disgust and that of others, until finally they expectorate a round piece of hard muco-pus, with the scab from the ulcer. The hawking is often so great that it leads to vomiting, and the symptom itself is a very annoying one. In a similar accidental manner as Dr. F., Dr. Hugo Engel discovered that Jensen's pepsin, if regularly used in divided doses (10 to 15 grains 3 to 4 times daily), especially if combined with muriate of ammonia (20 grains 3 to 4 times per diem), and with powdered extract of liquorice (same dose as the muriate), to improve the taste, is almost a specific in the complaint spoken of. Only one must be careful to obtain the genuine Jensen's pepsin, there being many similar but worthless preparations in the market, and they are substituted but too often for the genuine article on account of their great cheapness. The

tablets of Jensen's pepsin are well adapted for the purpose indicated, and may be taken separately from the sal ammoniac. In that case the aromatic powder may be omitted.

THE MICROBE IN HEREDITARY SYPHILIS.

How difficult it often is to discover the germ in infectious diseases, and how easily mistakes are made even by experts in bacteriology, the following incident taken from the *Deutsche Med. Zeit.*, No. 52, 1886, will prove:

Drs. Kassowitz and Hochsinger, in Vienna, had found in the tissues (skin of pemphigus, bones, liver, pancreas, lungs, and thymus) of five grave cases of hereditary syphilis a micro-organism which seemed specially characteristic by its size, form, and arrangement. The same microbe could never be discovered in the tissues of children not luetic. The micro-organism seemed to depend upon the lesions caused by hereditary syphilis. Its main seat is the vascular system and of the tissue nearest to the blood-vessels. The fact of these organisms being met with on the surface of the red blood-corpuscles, and only in organs to which the atmosphere has admittance, appeared to demonstrate the necessity of the presence of oxygen for the development of the microbe.

To determine whether it was really a special germ of its own kind the usual investigations showed a peculiar action of coloring matter, a characteristic chainlike arrangement of whole colonies and the relation already mentioned to blood-vessels. Rosenbach's pyogenic streptococcus exists only in the lymph-spaces of the skin, while that of erysipelas is found only with pus.

The specific germ of lues in its altered form of hereditary syphilis seemed to have been found; but the observers sent specimens of the newly-discovered microbe to Dr. Kolisko, of the Pathological Institute in Vienna. He succeeded by pure cultures and inoculations in proving the identity of the streptococcus described with the pyogenic one above mentioned, and he thus explained the reason why the microbe of K. and H. has been found only in grave cases of hereditary, and why not in acquired lues, viz.: because in the former alone pyogenic processes develop, the consequence of the presence of the pyogenic streptococcus.

POISONING BY OPIUM.

Dr. C. Plaster, in Munich (*Münch. Med. Wochschrift*, May 6, 1886), reports the case of a vigorous man, who, with suicidal intent, had swallowed about one drachm of a preparation of opium destined for smokers, a kind of dried aqueous opium extract. When he was brought to the hospital he was in the stage of severe depression, which manifests itself by utter cessation of all reflex excitability and of all voluntary motion. Emetics, dry friction, cold affusions, artificial respiration, and the injection into the œsophagus of strong black coffee, were without any result. But two injections of $\frac{1}{30}$ gr. of sulphate of atropia, each produced transient dilatation of the pupils and some improvement in breathing. Death, however, ensued in a few hours later.

The post-mortem examination showed hyperæmia of the brain and its membranes in an extraordinarily high degree, and this fact causes the author to ask the question, whether under such circumstances as those narrated, venesection was not the only means promising any success. We believe the suggestion a good one, for though it is admitted that venesection would relieve the fullness of the blood vessels but for a short time, the latter is all that is wanted in so grave a case of opium poisoning. If we only succeeded in re-establishing active circulation within the cranium for the shortest space of time possible, our other remedies would have time to eliminate the poison. Besides, blood-letting not only diminishes for a moment the amount of blood in the congested vessels, but by diluting the blood it diminishes the vis a tergo, lessens the existing hyperæmia more permanently, and stimulates absorption and increased activity of the skin. There is, however, another question to be inquired into: Do the large doses of atropia, if not successful in restoring the patient to life, themselves give rise to, or at least favor the congestion of the brain?

A PECULIAR EFFECT OF MASSAGE.

That massage has to credit many of its successes to the fact that it increases and stimulates the peripheral circulation is known, but Dr. Pogosher, of Moskau (*Sjetopissy Chirurg. Obchestwa u. Moskur*, 7, 86, Russ.), has recently discovered another important effect of manipulation.

He connected a sphygmograph with the radial artery of an arm, which was being manipulated by a masseur. He noticed that while the massage was practiced from the periphery towards the centre the arterial pressure was at first increased, later diminished. But if the movement take the opposite direction, viz., from the centre towards

the periphery, the opposite effect sets in, the arterial pressure first suffering a diminution, later an increase.

We learn from this discovery that by massage we may alter ad libitum the quantity of blood in the vessels, and it will be now only necessary to find out whether the same result may be obtained in disease as in health—a rather important point, considering that the experiments were made on a healthy person, and that most individuals for whom massage is mainly indicated generally suffer from some malady connected with morbid changes of circulation.

TUBERCLE-BACILLI IN SUPRA-RENAL CAPSULES.

The frequent occurrence of disease of the supra-renal capsules in Addison's disease is not only generally recognized, but no authenticated case has yet been recorded, where this malady had happened without a lesion. Various morbid changes of these parts have been reported, but the discovery of Rauschenbach—the presence of tubercle-bacilli in the supra-renal capsules in Addison's disease—seems to bring us a step further.

Rauschenbach's observations are published in the *Revista de Ciencias Méd.*, May 5, 1886. We see from his article, that only one drawback exists, which greatly imperils the usefulness of his discovery. The supra-renal capsules were not alone diseased; other parts of the bodies, examined by him, also were the seat of a tubercular process. We cannot assume, therefore, that the lesion of the supra-renal capsules in Addison's disease is always produced by the tubercle-bacillus; but we may say, that various morbid processes, when attacking the capsules, may give rise to the peculiar bronzing of the skin so characteristic of the malady in question. That phthisical patients often present a bronzing of their skin, sometimes greatly simulating Addison's disease, and not seldom really suffering from it besides their main tubercular lesion, has long been known.

NOTES AND COMMENTS.

Gumma in the Pons.

A case of a gumma in the pons, of extraordinary interest on account of a descending degeneration in the medulla oblongata and medulla spinalis, has been published by Dr. Pasquale Ferrare (*Estratta dalla Rivista Internat. di Medic. e Chirurgia*, 10, 1886).

The new growth had commenced remarkably early—about fifteen months after the primary affection. It started from the right lower portion of the pons, penetrated through the whole thickness of the latter to its left side, and had destroyed the pyramidal fibres, the ascending root of the trigeminus, and the oculo-motorius on the right side, while the facial fibres were compressed on both sides, and had partially been obliterated. During life the following symptoms indicated the existence of the lesion.

The right bulbus had deviated toward the inside and upwards, diplopia existed, further left-sided hemiplegia and hemianæsthesia, paralysis of both sides of the face and of the muscles of the pharynx, in consequence of which latter occurrence the voice had a nasal sound, the speech had become indistinct, and spontaneous deglutition was impossible, the act, when performed, being completely an involuntary one.

The secondary degeneration in the cord concerned the posterior lateral columns and the inner portion of the anterior; at the same time single fibres of the main bundle of the anterior column and of the lateral were affected on the left side, as also the gray substance of the left anterior cornu. Besides, there was noted as the consequence of a compression of the right pedunculus cerebelli a degeneration in the left rectiform body, in the left olive, and in the whole motor field of the left half of the medulla oblongata. Some peculiar anomalies in the course of some pyramidal fibres are also mentioned by the author, and in this fact we probably find the explanation of the somewhat erratic course of the descending degeneration.

Cases of larger single new growths due to lues are rather rare, and the question remains: Was the degeneration due to syphilitic dyscrasia, or did it have its origin from the tumor?—*i. e.*, was it caused by compression and thus by want of blood supply?

The Presence of Iron in Diabetic Patients.

In many cases a great quantity of iron is met with in the liver of persons suffering from diabetes mellitus, and some observers have gone so far as to look upon this augmented quantity as an evidence of diabetes. To determine the point whether iron is indeed always present in an increased degree in the liver and the spleen of such individuals, Dr. Zaleski has made a series of investigations (*Virch. Arch.*, *Bd.* 104, H. 1), and arrived at the following conclusions:

When present, the iron may show itself in two ways: either it penetrates all the tissues of the organism, or it forms special deposits,

where it gradually accumulates. In the first case it becomes an integral part of the cells; it does so most commonly in the liver and spleen. To discover it careful chemical and microscopical examination is necessary, while the microscope suffices in cases of special deposits.

Brownish, rusty-colored deposits of pigment, a very frequent morbid phenomenon, do not give the reaction of Fe in every case of diabetes, neither is siderosis of the organs in the sense of Quincke (Fe in the form of deposits), a common occurrence in that disease. The extraordinary quantities of iron in the liver and other organs also do not happen in every case of diabetes. In many cases Fe is met with as an oxide of iron albuminate, but, though in intimate organic union, it cannot be considered stabile. The Fe reaction, which, as has been contended, never succeeds when applied to the brain of a diabetic patient, does sometimes result. The normal quantity of iron in the blood of such individuals may also be greatly increased, as Zaleski has proved, contrary to the assertions of other observers.

Tympanites in Hysterical Women.

Professor Talma, of Utrecht, writing on tympanites in hysterical women, relates some interesting facts concerning three of his patients. He believes the cause of this condition to be spasmodic contraction of the diaphragm. The first case mentioned is that of a servant, aged twenty-three, who presented, with exception of paralysis, all the symptoms common to hysterical girls. She sought advice for an eruption on the breast, and whilst under Prof. Talma's treatment, mentioned that she had suffered some months previously from enlargement of the abdomen. The abdomen was even then greatly enlarged, and the girl suffered terribly from hiccough, which increased in violence when any of the students approached her. During sleep the size of the abdomen decreased considerably, and when the patient was put under chloroform it resumed its normal proportions. A tube was passed into the stomach, but no abnormal amount of gas was discovered, nor was any undue quantity found in the intestines. As the effect of the chlorofom passed off, the abdomen again increased in size, and Professor Talma noticed that the patient took four or five inspirations without any corresponding expirations. During respiration the abdomen was immovable, and the breathing entirely thoracic; the lower border of the lungs was depressed to the tenth rib. Prof. Talma was convinced that the enlargement of the abdomen was the result of spasmodic contraction of the diaphragm. The two other cases were those respectively of a servant, aged thirty-five, and a girl, aged fifteen, who had not menstruated. The cases were somewhat similar, and Prof. Talma came to the same conclusion as in the first case as to the cause of the tympanites.

Acromegalia.

In the *Revue Médicale* for April, Dr. Marie gave an account of some singular characteristics he had met with in two cases of acromegalia, taking the form of a non-congenital hypertrophy of the hands, feet, and head. The skeleton of the hands and feet was like a giant's; the soft parts had developed with the bones, consequently there was no apparent deformity. A singular contrast was observed in the forearms, the arms and legs retaining their ordinary size. The head was only large in some parts, although the skull was affected. Hypertrophy had especially developed in the bones of the face, the general aspect of which was that of an elongated ellipse. Minor characteristic deformities were noticeable. The vertebral column was bent forward; some of the bones had increased in size (clavicle, ribs, patella, and ilium); the long bones remained normal. The fibro-cartilages of the ear and larynx showed a tendency to become hypertrophied; the joints were only slightly altered in shape. The muscles were lessened in volume. There were slight blindness and deafness; sudden unexplained pains occurred, difficult to remove. There were a marked tendency to varicose veins and hemorrhoids, and intense thirst. More than the normal quantity of urine was passed. The skin remained intact, but the patient presented cachexia in a mild degree. Acromegalia attacks both men and women between the ages of 15 and 35; its etiology is obscure; excepting the absence of menses, thare are no definite symptoms. Dr. Marie believes that acromegalia is a bony malformation analogous to progressive primitive myopathy.

Tubercle Bacilli and Heredity.

Dr. Curt Jani has examined the healthy sexual organs of nine phthisical patients for tubercle bacilli. No bacilli were found in any of these cases in the semen from the vesiculæ seminales, but, on the other hand, in five cases out of eight a small number were found in the testicle and in four out of six in the prostate. There was no pathological

alteration in the tissues of the testes. Besides these cases, Dr. Jani found in one case of acute miliary tuberculosis numberless tubercle bacilli in the tissue of the prostate. He, further, examined two women who died of pulmonary phthisis, the ovaries both times presenting negative results. In one case of chronic pulmonary phthisis, with extensive intestinal tuberculosis, he examined the tubes and found tubercle bacilli. Dr. Jani is of opinion that the tuberculous poison may pass to the fœtus in two ways—through the semen of the male, and through the migration of the bacilli into the womb from the abdominal cavity. Infection of the ovum after impregnation by the placental circulation he thinks must be unusual, because the examination of the body of a woman five months pregnant, who died from acute miliary tuberculosis, in whom the general infection took place through the growth of a caseous mass in a pulmonary vein, showed that there were no tubercle bacilli either in the placental attachment or in the lungs, liver, kidneys, or the epiphyseal lines of the different bones of the fœtus. Dr. Jani, however, considers that it is by no means certain that in chronic miliary tuberculosis deposits may not form in the neighborhood of the placenta, and thus infect the fœtal organism.

Scabies.

The importance of recognizing this disease is certainly very great, for it is one of the few diseases that we can cure, while at the same time it is a disease that not only will not get well spontaneously, but while it lasts is constantly a centre for the spread of the affection. In the *Boston M. and S. Jour.* (September 23), Dr. F. B. Greenough says that scabies ought to be recognized (although his experience would show that it by no means always is) by the fact of lesions being found between the fingers, on the ball of the hand, and wrists, if not characteristic burrows, at least small vesicles; by the presence of characteristic lesions on the penis in the male subject; by the existence of secondary manifestations on the forearms, buttocks, abdomen, thighs and legs, more or less developed, as the case is of longer or shorter standing; by a decided increase of discomfort in the way of itching during the night, and by the fact that others who are thrown into intimate relations with the patient are similarly affected.

The treatment that he has used is the old sulohur ointment that Hardy introduced years ago at the St. Louis—one part of carbonate of potash, two of sulphur, and three of vehicle, for which he has taken petroleum ointment instead of lard. The objection to the use of sulphur is, of course, its irritating action on the eczematous and pustular secondary eruptions. Strict cleanliness must, of course, be enjoined.

Traumatic Pleurisy.

Dr. Seved Ribbing reports, in the Swedish *Eira*, amongst a number of instructive cases, the following one of traumatic pleurisy. A man, who had received a blow on the right side of the thorax in a drunken quarrel, was admitted into the Cimbrishamn's Hospital with the ordinary signs of pleurisy with effusion. The cavity was consequently aspirated, the puncture being made in the eighth intercostal space just below the angle of the scapula. The signs of fluid returning, it was decided to open up the cavity. This was done by an incision in the same situation as that in which the aspiration had been performed, and a quantity of thick fibrino-purulent matter evacuated, a large French œsophageal sound being used for drainage. Two days after the operation it was noticed that the integuments and superficial muscular layer around the shoulder-joint flapped like a curtain at each inspiration. As this pointed to the existence of an abscess cavity communicating with the chest, a sinus was searched for and discovered running upwards from near where the opening into the thoracic cavity had been made. This sinus was laid open, and, together with the chest, carefully drained and washed out with carbolized water. The quantity of fluid which came away dimished daily; the temperature, which had been high, sank; and in three months' time the man was discharged cured.

Blindness and Fecundity.

It has been asserted by Magnus, Fuchs, and others, that children, one or both of whose parents may be blind, are very liable to be themselves blind. Magnus investigated fourteen instances of married couples in whom one or both were born blind, or became blind at an early age, and found that, out of thirty-four children begotten of these marriages, eight, or 23.5 per cent., were either blind or weak-sighted. Mr. Simeon Snell reports, in the *British Medical Journal* of August 7, 1886, thirteen instances of marriages, one or both the contracting parties being blind, in which none of the children had any trouble with the sight nor any

trouble with the eyes. He noticed one curious fact, however, and that was the small proportion of births. There were ten men with sighted wives, and excluding one whose wife had ceased to bear children before his blindness came on, there were left nine, with twenty-six children between them, or less than three per family. Adding to this number three blind couples with two children, there was a total of twelve with twenty-eight children, or two and one-third per family. It would almost seem, therefore, that such marriages are less than usually fruitful. Farr placed the number of children per wife in England as 5.2.

Disease of the Nose Causing Aphonia and Dyspnœa.

Dr. Predborski mentions in the Polish journal *Gazeta Lekarska* a case of aphonia and spasmodic dyspnœa, where the cause was found to be an affection of the nose. A young Jewess, subject from childhood to attacks of epistaxis, received a severe nervous shock, being, in fact, the subject of an attempted violation. After this she completely lost the power of speech, and began to suffer from attacks of spasmodic dyspnœa; her catamenia also ceased. One of the attacks was so alarming that it was thought that tracheotomy would have to be performed, and preparations were made for the operation, but, on chloroform being given, her condition improved so much that she not only breathed more easily, but began to scream, so that all thought of operative procedures was abandoned. In a few weeks' time the girl seemed much better, but subsequently the symptoms reappeared. The nose, on examination, showed that the lower and middle turbinated bones on the left side were red and tumefied. When they were touched pain was produced, accompanied by sneezing and discharge of mucus. The application of chromic acid quickly and completely restored the patient to her usual state of health.

The Peroneal Type of Progressive Muscular Atrophy.

The thesis prepared by Dr. Howard Tooth for the degree of M. D. in the University of Cambridge contains valuable information and an excellent bibliography. The author of the thesis contends that there is a form of progressive muscular atrophy which commences in the lower extremities, most often in the peroneal muscles, but sometimes in the tibialis anticus, extensor longus digitorum, or gastrocnemius; that the hand and forearm muscles are attacked at an early period; that the disease is one of childhood; that heredity is a marked feature; that the disease shows a slight preference for the male sex; that fibrillar or fascicular tremors are frequently though not always present; that degenerative electrical reactions are often an early phenomenon; and, lastly, that from a record of necropsies, as well as from the clinical symptoms, it may be inferred that the disease is one affecting the peripheral nerves.

Mechanical Removal of Croupous Exudation After Tracheotomy.

After tracheotomy for croup, when it is found impossible to clear the trachea from membrane by forced expirations, suction, etc., Dr. Pievigzĕk, writing in the *Przeglad Lekarski*, advises the use of Schrötter's forceps, which, he says, should be so introduced through the wound that the blades may open antero-posteriorly, and not laterally, for fear of taking up the angle at the bifurcation of the bronchi. Sometimes it is possible completely to clear the trachea by one or two introductions of the forceps. In cases where the obstruction is in one of the bronchi, the patient should be laid on the corresponding side and the forceps inclined accordingly. Information may also be obtained as to the situation of the obstruction by the aid of a mirror introduced into the wound, the patient's head being at the same time thrown well back. The instrument which the author finds most suitable for this purpose is Zanfal's nasal speculum. He remarks that children bear the operation without any special trouble.

Cocainomania.

Erlenmeyer, in the *Deutsche Medizinal Zeitung* (1886, No. 46), has studied the symptoms in a number of individuals who have used cocaine to excess, by subcutaneous injection or otherwise. The characteristic symptoms denote vaso-motor paralysis, the pulse is accelerated, the sweats profuse, and dyspnœa and syncope ensue. Failure of general nutrition is very notable, the eyes become sunken, and the skin of cadaveric hue. At a more advanced stage psychic troubles supervene, sometimes requiring personal restraint. Most of the persons so affected had previously been addicted to the abuse of morphia, and cocaine had been resorted to as the minor evil. It would therefore be unjust to lay too large a share of the

troubles noted at the door of cocaine; still, enough evidence is at hand to prove that it may be productive of evil consequences, and should only be used as a powerful medicament with circumspection.

Ichthyol in Rheumatism.

Dr. Dubelir (*Russkaya Meditsina*, August 10, 1886,) reports eight cases of rheumatism treated by ichthyol at the Moscow Military Hospital. Six of the cases were acute, and two chronic. The preparation was used both internally and externally. The affected parts were first washed off with soap and water, dried, and then smeared with the ichthyo-sulphate of ammonium, and covered with cotton or flannel. After long use, or when the skin was insufficiently or not regularly washed, pustules were caused by the application. Internally the author gave fifteen to twenty-five drops of the ichthyo-sulphate of ammonium in a wineglass of water, or else administered the remedy in the form of pills of one and a half grain each, from six to twelve pills a day. In every case the pains were quieted, but the swelling of the parts did not disappear. The writer advises, therefore, that ichthyol be given in rheumatism only for its anodyne effects.

Henocque's Hæmatoscopic Method.

M. Hénocque exhibited to the Medical Congress at Nancy in August his apparatus for investigating the blood by *hæmatoscopy*. The process consists in first determining the amount of oxyhæmoglobin in the blood by the hæmatoscope, and then estimating the time required for its reduction by observing its passage across the thumb-nail through a direct vision spectroscope. The activity of reduction varies independently of the quantity of oxyhæmoglobin, being generally increased in persons of sanguine habit and in patients with arthritic and rheumatic diseases, and diminished in those with anæmia, chlorosis, epilepsy, temporary bilious disturbances, menstrual troubles, and in certain stages of phthisis.

A Recovery from Hydrophobia.

In the *N. Y. Med. Jour.* we read that in October of 1884 a physician now living in a neighboring city was bitten by a rabid dog. The wound, which was on the right thigh, suppurated; there was much constitutional disturbance, and, according to his own statement, a distinct and severe hydrophobic convulsion. The marks of the animal's teeth are still plainly visible; the affected thigh and its fellow are covered with reddish-brown maculæ varying in size from that of a large pin-head to that of a silver three-cent piece, and both thighs are exquisitely sensitive.

News and Miscellany.

Meeting of the Committees of Conference of the Various Special Associations requested to Participate in Conjoint Session.

In response to the notice issued by the Secretary of the Committee of Conference of the American Surgical Association, the Committees of Conference met at the Army Medical Museum, Washington, D. C., at 12 o'clock noon, on Friday, September 24, 1886.

The meeting was organized by the election of Dr. S. C. Busey, of Washington, Chairman, and Dr. J. Ewing Mears, of Philadelphia, Secretary.

The Secretary reported that he had received notification of the appointment of the following committees:

1. *American Ophthalmological Association*,—O. F. Wadsworth, M. D., Boston; C. T. Bull, M. D., New York; George C. Harlan, M. D., Philadelphia; Samuel Theobald, M. D., Baltimore; R. E. Freyer, M. D., Kansas City, Mo.

2. *American Otological Association*.—C. R. Agnew, M. D., New York; H. Knapp, M. D., New York; John Green, M. D., St. Louis; W. H. Carmalt, M. D., New Haven, Conn.; George Strawbridge, M. D., Philadelphia.

3. *American Gynecological Society*.—S. C. Busey, M. D. Washington; Fordyce Barker, M. D., New York; J. R. Chadwick, M. D., Boston; J. Taber Johnston, M. D., Washington; Thomas A. Emmet, M. D., New York.

4. *American Laryngological Association*.—J. Solis Cohen, M. D., Philadelphia; F. I. Knight, M. D., Boston; G. W. Lefferts, M. D., New York; F. H. Bosworth, M. D., New York; E. L. Shurley, M. D., Detroit.

5. *American Dermatological Association*.—H. G. Piffard, M. D., New York; F. B. Greenough, M. D., Boston; R. B. Morrison, M. D., Baltimore; L. N. Denslow, M. D., St. Paul, Minn.; G. H. Tilden, M. D., Boston.

6. *American Medical Association*.—C. H. Mastin, M. D., Mobile; C. T. Parkes, M. D., Chicago; N. Senn, M. D., Milwaukee; J. Ford Thompson, M. D., Washington; J. Ewing Mears, M. D., Philadelphia.

7. *American Neurological Association.*—L. C. Gray, M. D., Brooklyn; J. Van Bibber, M. D., Baltimore; E. C. Seguin, M. D., New York; Wharton Sinkler, M. D., Philadelphia; Philip Zenner, M. D., Cincinnati.

8. *American Climatological Association.*—A. L. Loomis, M. D., New York; F. Donaldson, M. D., Baltimore; F. C. Shattuck, M. D. Boston; E. T. Bruen, M. D., Philadelphia; W. W. Johnston, M. D., Washington.

9. *Association of American Physicians and Pathologists.*—Wm. Pepper, M. D., Philadelphia; Francis Delafield, M. D., New York; R. T. Edes, M. D., Boston; J. Palmer Howard, M. D., Montreal; J. T. Whittaker, M. D., Cincinnati.

The roll was called and the following members of the committees answered to their names:

1. *Ophthalmological Association.* — O. F. Wadsworth, M. D., Samuel Theobald, M. D.

2. *Otological Association.*—C. R. Agnew, M. D., W. H. Carmalt, M. D.

3. *Gynecological Society.*—S. C. Busey, M. D., J. R. Chadwick, M. D., J. Taber Johnston, M. D.

4. *Laryngological Association.* — F. I. Knight, M. D., E. Shurly, M. D.

5. *Dermatological Association.*—H. G. Piffard, M. D., G. H. Tilden, M. D.

6. *Surgical Association.*—C. H. Mastin, M. D., J. Ford Thompson, M. D., J. Ewing Mears, M, D.

7. *Neurological Association.*—L. C. Gray, M. D., J. Van Bibber, M. D.

8. *Climatological Association.*—F. Donaldson. M. D., W. W. Johnston, M. D.

9. *Association of American Physicians.*—Wm. Pepper, M. D.

Dr. Wm. Thomson, of Philadelphia, was present as a member of the committee of the Otological Association, in place of Dr. Geo. Strawbridge, who had resigned from the committee; and Dr. W. Hendrie Lloyd, of Philadelphia, was present as a member of the committee of the Neurological Association, in place of Dr. Wharton Sinkler, who had resigned.

On motion, it was resolved that the Associations represented should vote by title, taken in chronological order, and as a unit.

Dr. Wm. Pepper offered the following resolutions, which, after careful consideration and discussion by those present, were adopted separately, and then as a whole:

Resolved, 1. That it is desirable that the following societies—the American Surgical Association, American Ophthalmological Association, American Otological Association, American Neurological Association, American Gynecological Association, American Dermatological Association, American Climatological Association, Association of American Physicians and Pathologists—shall arrange for a conjoint meeting in the city of Washington, in the month of September, 1888, and subsequently at intervals of three years, at the same time and place.

2. That this arrangement shall not interfere in any way with the autonomy of each special society; and that each society shall retain the right to withdraw at any time from this conjoint scheme.

3. That the special feature of the meeting shall be the conjoint assemblage of the special societies on two evenings during the session; on one of which there shall be an address delivered by the President of the conjoint meeting, and on the other there shall be communications by a referee and a co-referee on some subject of general professional interest.

4. That each special society approving this report is invited to appoint one representative (with an alternate), and that the representative so appointed shall constitute an executive committee to serve for one year, with power to elect such officers for the first conjoint meeting as may be deemed necessary; to prepare a programme for said meeting; to make all other necessary arrangements; and to prepare and submit a plan of organization for future meetings.

5. That all expenses connected with the conjoint sessions shall be apportioned equally by the executive committee among the special societies participating.

Owing to the views entertained by the committees of the Ophthalmological and Dermatological Associations with regard to intervals of times of the meetings, they abstained from voting upon the first resolution.

The Secretary was instructed to send to the medical journals of the country a report of the proceedings of the meeting, a printed copy of the same to each member of each Association participating, and a certified copy to the Secretary of each Association.

American Academy of Medicine.

The tenth annual meeting will be held in the chapel of the First Presbyterian church, Wood street, near Fifth avenue, Pittsburgh, Pa., Tuesday and Wednesday, October 12th and 13th, 1886.

TUESDAY, OCT. 12, AT 10 O'CLOCK A. M.

Opening of session, with prayer; reading of minutes of last annual meeting; report of council; election of fellows; amendments to

the constitution and by-laws; appointment of Committee on Nominations; new business.

Report on the Present Working of Laws Regulating Medical Practice, by Richard J. Dunglison, A. M., M. D., of Philadelphia, Pa., and Henry O. Marcy, A. M., M. D., of Boston, Mass.

Reading of papers:

"The Best Equipment for Medical Study." By Frederic H. Gerrish, A. M., M. D., of Portland, Maine.

"The Two Standards, Literary and Medical." By R. Lowry Sibbet, A. M., M. D., of Carlisle, Pa.

AT 3 O'CLOCK, P. M.

New business. Report of Standing Committee on the Requirements for Preliminary Education in the various Medical Colleges of the United States and Canada. Report of Special Committee on the best Preliminary Education for Medical Students.

Reading of Papers:

"The Status of Medical Education in the United States." By John D. Kelly, A. M., M. D., of Lowville, N. Y.

"The Advantages of a Classical Education to the Medical Student and the Physician." By L. P. Bush, A. M., M. D., of Wilmington, Del.

"A Christian Education the Best Preparation for the Practice of Medicine." By Andrew C. Kemper, A. M., M. D., of Cincinnati, Ohio.

"Prolonged Gestation." By J. Cheston Morris, A. M., M. D., of Philadelphia, Pa.

AT 8 O'CLOCK, P. M.

Address by the President, R. S. Sutton, A. M., M. D., of Pittsburgh, Pa.

AFTER THE PRESIDENT'S ADDRESS.

Annual collation of the Academy at the Hotel Duquesne, Smithfield street, opposite City Hall.

Tickets for the collation (fixed, by resolution of the Academy, at two dollars each) may be obtained by remitting the amount to Dr. S. N. Benham, 156 Third avenue, Pittsburgh, Pa.

WEDNESDAY, OCT. 13, AT 10 O'CLOCK, A. M.

New business. Treasurer's report. Report of Committee on Nominations.

Reading of papers:

"The Duties of Physicians to each Other." By Traill Green, A. M., M. D., of Easton, Pennsylvania.

"The Medical Service of the United States Pension Bureau." By Phineas S. Conner, A. M., M. D., of Cincinnati, Ohio.

"The Treatment and Management of Tubercular Spondylitis." By Virgil P. Gibney, A. M., M. D., of New York, N. Y.

"Is Modern Wound Treatment Scientific?" By Henry O. Marcy, A. M., M. D., of Boston, Mass.

"Physical Culture in Amherst College." By Nathan Allen, A. M., M. D., of Lowell, Mass.

"What Should Physicians Advise as to the Education of Young Women?" By George E. Stubbs, A. M., M. D., of Philadelphia, Pa.

"The Relation of Specialism to General Medicine: Is it a Result of a Higher Education?" By William S. Little, A. M., M. D., of Philadelphia, Pa.

New business. Induction of President-elect. Appointments for ensuing year (additional members of council; Standing Committee on Requirements for Preliminary Education. Unfinished business. Adjournment.

AT 1:30 O'CLOCK, P. M.

The Fellows are invited by Dr. R. S. Sutton, President of the Academy, to take lunch at his residence, 419 Penn avenue.

College of Physicians of Philadelphia.

At the meeting of the College held on Wednesday evening, October 6, Dr. Henry Hartshorne read a memoir of the late Dr. Edward Hartshorne; Dr. Ruschenberger, "An Account of the Institution of the College of Physicians of Philadelphia;" and Dr. Thomas B. Reed described a plan for a Children's Ward at the Presbyterian Hospital.

NEW BOOKS ADDED TO THE LIBRARY DURING SEPTEMBER, 1886.

Irregular Medical Schools.

The *Jour. Am. Med. Ass.*, October 2, says that the Iowa State Board of Health will not recognize diplomas from the following colleges: American Eclectic College, Cincinnati; American Health College, Cincinnati; American University of Pennsylvania (Buchanan), Philadelphia; Beach Medical Institute, Indianapolis; Bellevue Medical College of Massachusetts; College of Physicians and Surgeons, Buffalo, N. Y.; College of Physicians and Surgeons, Milwaukee; Eclectic Medical College of Philadelphia; Edinburgh University, Chicago and St. Louis; Excelsior Medical College, Boston; Hygeo-Therapeutic College, Bergen Heights, N. J.; Hygeo-Therapeutic College, New York City; Joplin Medical College, Joplin, Missouri; Livingston University, Haddonfield, N. J.; Medical Department of the American University of Boston, Boston; New England University of Arts and Sciences, Boston; New England University of Arts and Sciences, Manchester, N. H.; Penn Medical University, Philadelphia; Philadelphia University of Medicine and Surgery, Philadelphia; Physio-Eclectic Medical College and Physio-Medical College, Cincinnati; St. Louis Eclectic Medical College, St. Louis; St. Louis Homœopathic Medical College, St. Louis; Curtis Physio-Medical Institute, Marion, Indiana; American Anthropological University, of St. Louis; Medical Department of Drake University, Des Moines, Iowa; and King Eclectic Medical College, Des Moines, Iowa.

Scottish Mediæval Medicine.

The ninth King of Scots, if we may believe the early chroniclers, rendered his reign memorable by the high honor in which he held physicians. It was in Ireland, where he spent years of exile with his father, says Buchanan, that he became familiar with medicine and its practitioners. When settled on the throne of Scotland he so inspired the courtiers with his medical tastes that the healing art, particularly surgery, became quite a patrician accomplishment, and for centuries afterwards "nemo esset in Scotia illustriore loco natus, qui vulnerum curationem non teneret." Even down to the sixteenth century surgery, especially military surgery, was a *métier* in which the Scottish aristocracy were proficient. The gallant King James IV. pursued, according to Buchanan, the traditional practice of his race and ancestry with much zeal. "Unum e vetusta gentis consuetudine hausit avide, ut vulnera scientissime tractaret; cujus rei peritia toti Scotorum Nobilitati, ut hominibus in armis assidue viventibus, fuerat priscis temporibus communis." (One thing he imbibed eagerly from the ancient custom of the Scots—to wit, the thoroughly scientific treatment of wounds: a department in which, from remote times, the whole Scottish nobility, as men living constantly under arms, had shared a common skill.)

Cholera in Hungary.

The number of those attacked by cholera at Buda-Pesth is again on the increase, say advices from Vienna of the 19th ulto., whereas the fatal cases are not so numerous. From the 12th to the 18th of September, 61 cases of sickness and 19 deaths occurred. The Cholera Commission has discovered practices dangerous to health. In each of two houses belonging to a nobleman there were discovered from 150 to 200 persons lying together on the bare ground in the courtyard. In a cellar, 40 persons of both sexes were found sleeping together on the

ground. A number of such dwellings have been visited. In Vienna and Lower Austria, strenuous preventive measures are being adopted, although there has not as yet been reported a single case of cholera. The Servian Government has decreed a seven days' quarantine for travelers and goods coming from Hungary. At Odessa, a fourteen days' quarantine has been decreed for goods arriving from the Danubian ports. The five days' quarantine imposed at Constantinople consists, it is stated, in remaining five days on board of a steamer at the entrance of the Bosphorus. Fumigation is not regularly applied. There is, it is said, no chance of an early suppression of this quarantine.

An Undesirable Experiment.

A recent incident in the Michigan College of Medicine has been a source of much anxiety to more than one of the parties concerned. One of the professors of clinical medicine was giving his final lecture to the class on the subject of venesection. No patient being at hand upon whom the operation could be performed, the lecturer asked for a volunteer. One of the students responded, and was bled. The demonstration was successful; but subsequently inflammation of the wound supervened, followed by abscess, erysipelas, etc., and caused the gravest anxiety to the student, his parents and fellows, and to the operator himself. Fortunately, the patient is convalescent. The incident is one which may well be borne in mind by would-be observers. We are already familiar with experiments on the human subject, which, whatever their value as arguments, have led to more or less serious consequences. The experimenters were in many cases students, and were, therefore, probably undeterred by consideration for their wives and families; but certainly some caution is desirable, since a fatal result would, in all probability, result in a verdict of manslaughter against the victim's accomplices.

Prohibition "Beverages."

David W. Judd writes from Iowa to the *American Agriculturist:*

However much the citizens of Iowa may disagree as to the prohibition laws, provided for by both the State Constitution and the votes of the Legislature, strangers cannot be otherwise than impressed with the remarkable effects of these prohibition enactments; and the innovation often borders on the humorous. For example, instead of seeing, as in the saloons surrounding the railroad depots in other States, such "bulletins" as "Old Crow," "Whisky Punches," "Hot Scotches," "Kentucky Blue Grass," etc., etc., one is informed by the placards in saloons surrounding the depots at Des Moines and other points in Iowa, that "Hot Coffee," "Hot Tea," and "Pure Lemonade," etc., etc., are "served up here." Of course this order of things provokes no little opposition. But wait, say the earnest advocates of temperance, until you read the reports, after two years, from our Iowa prisons and jails, until you see how much our taxes are reduced by the absence of murder trials, and the expenses attending all the other crimes and excesses resulting from "free rum."

How to Detect a Morphine-Taker.

Professor Bull, of Paris, states that there are two ways by which the morphine habitué can be detected, and these are to be found in the skin and in the urine. The skin will be found to be covered with little dark spots situated in the centre of little indurations about the size of a large shot. It is needless to add that the indurations are the result of the little wound of the needle, but as these lesions are generally found on the inside of the thighs, the patient refuses to let them be seen, and in that case examination of the urine will prove of great service. A few drops of tincture of iron are put into the suspected liquid, and if morphia be present a blue tinge will be produced.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED SEPTEMBER 25, 1886.

Bailhache, P. H., surgeon. Granted leave of absence for thirty days, September 25, 1886.

Vansant, John, surgeon. Granted leave of absence for thirty days, September 24, 1886.

Bratton, W. D., assistant surgeon. Relieved from duty on Revenue Steamer "Corwin;" ordered to duty at Marine Hospital, San Francisco, Cal., September 20, 1886.

Therapeutic Notes.

Platt's Chlorides.—As the prevention of disease becomes of increased importance with the progress of medical science, so will the use of disinfectants as sanitary agents. Of the many which are now obtainable, we may specify as of marked excellence the

combination of chlorides sold by Mr. Platt and described in our advertising columns. They are particularly useful in the sick room, and there is a special call for their exhibition during the winter season, when houses are closed from the external air.

A Brutal Physician.

A French journal states that a physician was called in the night to see a woman in childbirth. The labor was complicated, and an operation was necessary, for the performance of which the physician demanded 250 francs in advance. The husband was a laboring man, and had but 100 francs, which he offered, with promises to pay the balance. The doctor refused in spite of the man's entreaties. Before another physician could be obtained, the woman died in great agony, two lives having thus probably been sacrificed for the paltry sum of thirty dollars.

Veterinary Medicine.

New York is the only State as yet which has undertaken to regulate the practice of veterinary medicine and surgery. A law has been passed requiring the registration of all practitioners with the evidence of proper qualification afforded by a diploma from some legally incorporated college or a certificate from an incorporated veterinary society. The first class in veterinary medicine, consisting of five members, graduated from Harvard University, June 30.

Another Hermaphrodite.

Among the replies to an advertisement of a musical committee for "a candidate as organist, music-teacher, etc.," was the following one: "Gentlemen—I noticed your advertisement for an organist and music-teacher, either lady or gentleman. Having been both for several years, I offer you my services."

Association of the Surgeons of the Pennsylvania Company.

The eighth semi-annual meeting of this Association will be held at the Seventh Avenue Hotel, Pittsburgh, Pa., Tuesday October 19, 1886, commencing at 9 a. m., Eastern time. A number of papers on appropriate subjects are promised.

Loomis Laboratory.

This is to be the name of a new building for the medical department of the University of New York, for the construction and maintenance of which $100,000 has recently been contributed by a gentleman who, for the present, withholds his name from publication.

Personal.

—Dr. S. D. Risley has removed to No. 1722 Walnut street.

Items.

—The seventh volume of the "Index Catalogue of the Library of the Surgeon-General's Office" has just been issued. It brings the index down to "Leghorn."

—Dr. Pekelharing, Professor of Medicine in the University of Utrecht, has been instructed by the government at the Hague to proceed to Acheen to make special inquiry into the nature of the malady known as "beri-beri."

—A gratuity of £10,000 has been granted from the Bavarian civil list to the widow of Professor von Gudden, of Munich, who perished with the late King of Bavaria in the lake at Castle Berg. He left a family of eleven children.

—The number of students in the Imperial University of Tokio is said, by the *Medical Record*, to be nearly one thousand, a large proportion of whom are students of medicine. Five of the professors in the medical faculty are Germans.

—The State Board of Health suffers a severe loss in the resignation of Dr. E. M. Moore, of Rochester, which has just been announced. Dr. Moore was one of its original members, and has always been one of the valuable and active workers in its service.

—A novel way of reassuring a patient was lately resorted to by a dentist in Mexico. A patient was to have a tooth extracted, but the preparations so frightened him that he declined to submit to the operation. To allay his fears, the dentist made his office boy open his mouth, and in a twinkling took out one of his teeth. We are not surprised to learn that the little fellow threw up his situation at once.

—The Paris Municipal Council have decided to open a hygienic museum, in which the microscopic effects of allowing water to stagnate, the skin to remain dirty, and bad air on the blood, will be shown, as well as other causes of disease. Lectures on the laws of health will be delivered in connection with the exhibition.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Lecture.

CARDIAC DEGENERATION.*

BY PROF. WILLIAM H. DRAPER, M. D.,

Of New York.

Gentlemen: The physiognomy of this man is a very characteristic one, and it is just such as you often see in hospitals, when cardiac and renal disease attack the obese and dissipated.

The history of this man has not yet been taken, but he says that he is sixty-two years of age, and he weighs 215 pounds. He has been a policeman on night duty ever since the riot of 1863, and he has been able to do that duty satisfactorily until the past two or three days, and now he finds himself embarrassed by asthma, as he says. You are to understand by this that he uses the term asthma as some professional men often use it, in a general sense. We do not as largely as we should confine that term to the strict definition of that neurosis with a distinct spasmodic character, which is true asthma.

Now, we will proceed at once to the objective examination; and let us suppose that this man could tell us nothing about his subjective history, and let us see how far towards the diagnosis the objective examination will lead us, without asking him any questions.

Inspection.—In the legs there is moderate œdema, and some varicosity of the veins. Then, as we come higher up, we find a very protuberant belly, which may be wholly due to the deposition of a large amount of fat, or partly to that and partly to the distension of the peritoneal cavity with water, gas, or something else. And this is the point to determine by further explorations.

Percussion.—I get some dullness in the line of the posterior spine of the ilium on the left side of the abdomen, but that may be due to deposition of a thick layer of fat. I find dullness in the same line on the right side of the abdominal cavity; but elsewhere there is resonance. There is a visible fluctuation such as you will often see in as fat a belly as this, and I do not think that there is any fluid in the abdominal cavity. The region of hepatic dullness extends below the ordinary line, and well up towards the nipple. I find no evidence by percussion of any considerable cardiac hypertrophy, and the cardiac pulsation is so feeble that I cannot find the apex beat. On percussion of the chest I find very good resonance in front, or perhaps an exaggerated degree of resonance, especially when you consider the thickness of the layer of fat which is lying over the chest walls.

Auscultation.—The respiratory murmur is very good on both sides, but better upon the left. There is nothing in the way of a cardiac murmur, but simply a reduplication of the first sound of the heart. The inspiration is feeble and the expiration prolonged, and I get some moist and sonorous rales at the base of the lungs at the end of inspiration. There is no evidence of any pleuritic effusion, and the breathing is of that sort which is common in persons with some emphysema and chronic Bright's disease. Now, it would ordinarily be necessary for us to examine the urine before going farther in making the diagnosis. But the man has stated to us that the physician who attended him outside, said that he had Bright's disease. The ex-

*Abstract of clinical lecture.

amination of the urine, however, would have enabled us to determine this with only the objective signs to aid us. It is sometimes necessary to make this examination at the bedside, and so it is important that you should always have the means ready for drawing off and examining the urine. Now, we will suppose that we have examined the urine and found albumen in it. What other means of obtaining information could we seek for? We can observe the tongue; and here we find it rather pointed, shaky, and a little dry; and its appearance to me, or to any one accustomed to examine the tongues of hospital patients, would be extremely significant. Again, there is something else significant about him, and that is the appearance of the nose, and the skin of the cheeks. In both there is a very pronounced redness, and the follicles are very large, and the skin of the face is very coarse and has a rather hypertrophic look. He has what would be described by a dermatologist as an acne rosacea, and a consequent hyperplasia of the skin, that means in the great majority of cases alcoholic indulgence. And that, with the appearance of the tongue, and these quick, sharp, restless movements which you have observed, means that this man has been for a long time abusing the use of stimulants. But he says that he is not a hard drinker, and only takes occasionally, while on duty, a little birch beer or whisky. Now here, gentlemen, you see what you get when you come to the subjective history. What he says is entirely the opposite of the conclusions which we drew from the objective examination. But I would still believe in the correctness of my own opinion. This man does not intend to deceive, but he tells you the story which you will hear very often, and even from many patients of intelligence, and that is the very best story that he can tell.

Now, we have completed the objective examination, and we have come to several conclusions. First, that he has albuminuria; another, that he has a very weak heart, probably from muscular degeneration; another, that he has degenerated vessels, for the radial arteries are stiff; another, that he has a chronic bronchitis, and some pulmonary congestion; and another, that he has lately been trying to make himself feel better by taking an occasional glass of stimulant, and has thus aggravated rather than bettered his general condition.

The first thing to do in the treatment of this case is to purge him immediately, to relieve the pulmonary congestion, and also with the view of getting out of the blood vessels some of the alcohol which is circulating in them. And then we shall be better able to see how far the general tissue changes and the morbid state of the vital organs has gone, and how far they are susceptible of relief. The true state is now somewhat masked.

SOME INTERESTING PATHOLOGICAL SPECIMENS FROM A TYPHOID PATIENT.*

MEDICAL CLINIC BY MORRIS LONGSTRETH, M. D.,

Of Philadelphia.

The patient from whom the specimens were removed, died after being in the hospital two weeks; he was admitted complaining only of two days' illness. Had had chill, headache, and was drowsy. Some fever and looseness of bowels. On admission, his temperature was 102⅖°, but that night rose to 104⅖°; still higher the night following; then each rise was followed by a slight fall, though not the same as in normal typhoid fever. His nails were blue, the stools characteristic typhoid stools, and typical rose-colored spots; in fact, there were all the evidences of typhoid. Still, from the condition of the lungs and hectic, early tuberculosis was evident.

Lungs were congested, and auscultation revealed numerous rales. Though in life we found no real evidence of deposit, after death we find it, and also a condition of *general sepsis.* The patient had valvular heart disease, and as a result, alterations in the spleen, which probably terminated his life.

This organ is penetrated in various directions with large cavities—here a white spot, there a large broken-down mass. What are these masses? I notice all these cavities have a *lining membrane,* and contained hardened matter, which is not tuberculous, because tubercle never forms a capsule, or lining membrane; nor a morbid growth, for the same reason. We are therefore practically limited to emboli. (?) A bare possibility exists that it is abscess, but this is rare, for the patient would have died long before this condition was reached, and this is evidently of long-standing. It must have required at least six months to form this dense fibrous membrane. Let us trace the source of the embolus. There is nothing in the present condition of the heart to account for embolus; the source itself must be old, and

*Abstract of clinical lecture delivered at the Pennsylvania Hospital.

I find, to begin with, evidence of old endocarditis—evidence of inflammation capable of giving rise to embolus. The valves are thickened, and there is a white line along their edges; but this is not all, for immediately beneath is the pink line showing there was, at one time, an accumulation of fibrine on the valves, which was washed off by the blood-current and carried into the circulation, leaving the valves smooth.

He had a distinct mitral regurgitant murmur, and I find the mitral valves thickened. Going on to the aortic valve, it also is found thickened and fenestrated. These are just the sort of valves which in their fresh state of injury give rise to embolism. Here is also a fatty heart due probably to the insufficient supply of blood sent for its nourishment during life. A good mode of determining fatty heart is to squeeze the organ between the fingers and thumb, and the sensation is as if the muscular fibre were disappearing from beneath the touch.

The liver bears no evidence of acute inflammation, but presents the usual condition of typhoid fever. The intestines present nothing unusual. Peyer's patches contain the typical typhoid ulcers. A word here about how to distinguish typhoid from tubercular ulcers. Each has its own perfectly characteristic appearance. The base of typhoid ulcer after it is well formed where it is stained with feces is not complete, and the base is thin. The reason is that the point at which ulceration begins is in the follicles of Peyer's patches, elevating the patches as the abscess forms beneath the mucous membrane; the membrane lifts up like a trap-door to let out the matter. I have seen the mucous membrane covering one of these areas of ulceration completely lifted off and found in the stools. This inflammation, which begins in the sub-mucous layer and extends downward, the more the inflammation the more the swelling and the greater the danger of extending into the muscular coat, which, if it reaches down to the inner layer, there is perforation of the bowel, and hence whatever increases the fecal accumulation and pressure greatly increases the danger of perforation; while in tuberculous ulcer the base is thick, for the lymph is deposited layer upon layer, and upon the peritoneal surface as well. This is, I think, a safer guide in distinguishing these two forms of disease than the ordinary description given in books, *i. e.*, one running lengthwise with intestine, the other round—this is not reliable, for it is according to the relation of the intestinal vessels.

MEDICAL CLINIC—SERVICE OF DR. HUTCHINSON.

TREATMENT OF PERITYPHLITIS.

Robert Stone, aged 22, born in England, has been in hospital two weeks. Up to that time he had always enjoyed fair health, though at one time had some slight spitting of blood, which caused no trouble. His present attack was immediately following a heavy oyster feast. He was attacked with severe cramps, but started for work, and was soon picked up in a faint, and carried to hospital.

On admission, the urine was found normal, abdominal tenderness and pain, local of right side; peritonitis; bowels constipated. There was slight dullness at apex of right lung, and a functional heart murmur. His temperature was 104⅕°, and the pain in the abdomen quite severe. Large doses of opium were administered to prevent action of bowels, and the next day temperature fell to normal, but rose again on the day following. Opium was continued for five days.

In local peritonitis the typical position of flexed limbs is not always present, but in this case it was. This was probably a case of typhlitis and perityphlitis, which set up a local peritonitis — the immediate active cause being the large amount of oysters eaten. There was an unusual amount of pain and uneasiness from the first in this case. Typhlitis, or perityphlitis, should always receive active and prompt treatment, for it is a disease prone to advance, and may become, by extension of inflammation, extensive, even fatal peritonitis, or may have abscess from inflammation extending to the cellular tissue.

As to treatment: Keep bowels quiet, prevent peristalsis by large dose of opium, carefully watch respiration, but keep patient under opium while pain and tenderness continue; no remedy likely to do this with half the efficacy of opium. Inunctions of the oleate of mercury continued till gums are slightly touched, but avoid all purgatives. Nourishing food, but of a kind that will not distend the bowel—milk, beef tea, etc.

For this patient, five days after admission, when symptoms had subsided, we relieved the bowel by an enema, which was followed by a small stool. After convalescence on fifth day, there was a recurrence of rise of temperature, which cannot be easily accounted for. We thought possibly we might be treating with a tuberculous patient, but subsequent observation did not confirm this supposition; but on the whole, his condition is interesting. When I first saw him he was

in a state of collapse, prostrated; could not pass water. Though apparently convalescent, he cannot be allowed to leave hospital for some time, and will remain under observation.

COMMUNICATIONS.

OBSTETRIC FORCEPS.*

BY D. BENJAMIN, M. D.,

Of Camden, N. J.

GENTLEMEN: In lieu of preparing a paper on some medical subject, as requested by you, I shall simply make a few extemporaneous remarks on the subject of obstetric forceps.

It has been said that the obstetric forceps have relieved more suffering and pain of woman than any other invention or discovery known to the science of medicine. In view of the discovery of chloroform and ether, this can hardly be considered as absolutely true, but certain it is, that in the hour of her greatest need and suffering, the obstetric forceps has been a friend indeed to woman.

Since the invention of the forceps by Chamberlain in the beginning of the seventeenth century, there have been numerous modifications, changes, and improvements, and when we look at these original straight forceps of Chamberlain, it is a matter of surprise that so much could have been accomplished with them, and how many difficult cases have been and can be delivered by their aid. Another thing worthy of remark in this connection is the fact that the cephalic curve of those original instruments has scarcely been improved, if it has been improved at all, in any of the modern instruments.

Without going into a detailed history of the various instruments that have been introduced as modifications of the original Chamberlain forceps, I will confine myself more particularly to the two leading forceps of the day, viz., the "Simpson" or short forceps, and the "Hodge," and Wallace's modification of the "Hodge," long forceps.

For many years, Professor Penrose, of the University of Pennsylvania, has been highly recommending the Simpson forceps, and I recollect that, after using the Hodge forceps for awhile, I purchased a pair of Simpson forceps, and have been using them for a number of years. I found on a number of occasions, as the Professor had remarked, that no forceps could compare with them in the ease with which they could be applied, and in safety to the patient while being operated upon, and with this pair of Simpson's forceps which I hold in my hand I have delivered cases, in consultation with other physicians, where both the Hodge and Wallace's modification of the Hodge had utterly failed to deliver the child successfully.

In one instance the pubic artery had been cut and the vagina tamponed while I was sent for, and in two cases the child's occipital bone had been crushed.

I have also frequently noticed that in the many cases in which I have delivered with the Simpson forceps, in none of them have I ever marked or cut the head of the child, and in no case do I know of ever having injured or bruised the mother in any way, so that I have come to regard them as perfectly safe and incapable of harm to either the child or the mother, so long as the traction is properly applied, and the curvature of the pelvis borne in mind by the operator. One or two of the cases to which I refer will be remembered by one or two of the physicians present with us to-day.

Another matter which I have noticed particularly with the Simpson forceps, is that never in my experience have I known them to slip; and this is a very important consideration, for the slipping of the forceps is not only very dangerous to the child, but extremely dangerous to the mother, and has, perhaps, caused as much injury as any other accident in the use of the instrument.

In holding up these forceps alongside of the Hodge, or Wallace's, you can easily see that when the two pairs of forceps are closed, as I now hold them, and as they would naturally be held in an attempt at delivery, the blades of the Simpson are much wider apart than they are in either the Hodge or in Wallace's modification of the Hodge; you will notice that the Simpson forceps cannot dangerously or injuriously compress the head of the child, while the Hodge, and especially the Wallace modification of the Hodge, will, in almost every case—perhaps in ninety-nine out of one hundred—which will be delivered by the aid of the forceps, compress the head of the child very much, and if the fœtal head is compressed to the fullest extent permitted by these two last-named instruments, there is great danger not only to the brain of the child, but even to its life, unless the head be a very small one, as the greatest diameter between the blades of the Hodge and of Wallace's modification

*Address delivered before the Medical Society of Camden, N. J., annual meeting, September 23, 1886.

of the Hodge is scarcely more than two inches. But, as in most cases the Hodge and the Wallace forceps are not pressed as closely together as they will go, it will be found that the handles will be spread apart nearly one inch. When I spread the handles three-fourths of an inch to one inch, the blades will occupy about the position they would be in when applied to an ordinary fœtal head. You will observe in that case that they are about as far apart in the middle of the blades as the Simpson forceps when the handles of the Simpson are entirely closed; but you will see, when I hold them up together in this way, a very important difference, viz., that while the blades of the Hodge or the Wallace are almost parallel from the middle of the blades to the points, the pulling part of blades, the blades of the Simpson forceps have quite a strong curve, and this is evidently the reason why the long forceps frequently permit the head to slip from their grasp.

By placing my hand between the blades of the forceps in this way, in imitation of the fœtal head, you will see how readily it can be pulled out from the grasp of the Hodge or the Wallace; this is not the case, however, with the Simpson forceps, as they still have, when spread sufficiently to grasp the ordinary fœtal head, such a curvature as will not permit the head to slip, or the blades to spread easily. You will observe further, in comparing the cephalic curves of these different instruments, as I hold them up, both closed, that the points of the long forceps come very close together—about one-fourth of an inch apart. This compels them, when compressed by the hands of the practitioner, to slip either back of the neck of the child and back of the occipital bone, or forward, which is an additional reason why they should slip their grasp, as in no case could the neck of the child, or the base of its head, be so closely compressed as that; and the slipping either backward or forward not only endangers the life of the child, but, as you see, with their strong, sharp pelvic curve, the points of the forceps are either thrown injuriously against the mother's tissue in front, or the broad, convex surface against the mother's tissue posteriorly. Indeed, I regard them as very formidable instruments, capable of great compression and traction, when you can get them properly adjusted, and to hold. In *some* cases, however, I have found them better suited than the Simpson forceps, but not in the general run of cases in which forceps are used, and I certainly regard them as a more dangerous instrument than the Simpson, especially in the hands of the inexperienced, as the long handles give them great leverage and power.

Having mentioned some of the objectionable features of these long forceps, I would now mention some of the features of the Simpson which are also objectionable:

1. I found quite a number of cases where they were too short, either from obesity of the patient or the high position of the child; and,

2. From the want of a little more pelvic curve, the handles could not be sufficiently depressed to bring the blades well down upon the cheeks of the child or towards the base of the skull.

In view of these objectionable features in the different instruments, I got in the habit of carrying both the Wallace and the Simpson forceps, for I believe that in most cases where the Simpson cannot be used the Wallace would be applicable, not only on account of its great pelvic curve, but also on account of the length of its handles. It then occurred to me that if I could eliminate some of the objectionable features from the Wallace forceps and some of the objectionable features from the Simpson forceps—in other words, produce a forceps that would possess the good qualities of each—I could often do away with the necessity of carrying two or three pairs of forceps, and thus save time, and danger to the patient. Acting upon these thoughts I have produced this forceps which I now hold in my hand. You will observe that they have the Simpson blades, the Simpson cephalic curve, with a slightly increased pelvic curve. You will also see that they have the long handles of the Hodge and Wallace forceps, with the blunt hook which the Simpson forceps have not, and you will see, especially, that I have lengthened the shank and given them the Simpson lock and removed the wood. This gives them all the ease of application, all the safety to mother and child, all the firmness and grip of the Simpson forceps, with all the leverage and power of the long-handled forceps. The long shank is also a very good feature, as it enables the operator to apply them with ease above the superior strait as at the inferior strait, while at the same time you have the opening between the shanks through which to insert the finger, either for the purpose of traction or for the purpose of touching the fœtal head, also avoiding the frequent and troublesome pinching, which every practitioner must have noticed the short forceps of Simpson inflicted upon the patient

when an attempt was made to apply them high up. The spreading of the shanks is also an advantage, and the danger of tearing the perineum by the spread of the shanks before the fœtal had has become engaged in the external opening of the vagina, spoken of by Professor Hodge, is purely imaginary, as no forceps ever spread sufficiently in front of the child's head to cause a rupture of the perineum; at the same time should they spread sufficiently to cause a stretching of the perineum, it would only save the operator the trouble of the constant and frequent stretching by the fingers, now recommended in all cases to precede the pressure of the head upon the perineum.

It is claimed that this modification of the Simpson forceps will do *all* that the original does, and something *more*. That there is no wood, crevices, or seams to carry infection. That they are safer and easier of application than the Wallace, and therefore better adapted for *general* use, and for recent graduates.

No forceps, however, has ever been invented that will meet *every* case. Occasionally a special case will be found for some other shaped instrument.

In this connection I would like to mention a fact that has frequently been impressed upon my mind, and which I do not remember of having seen mentioned, viz: That the head does not push itself through the mouth of the womb in all cases, but that in, perhaps, the majority of cases, the shortening of the womb pulls its mouth back from over the head of the child. In other words, the child's head may come completely through the mouth of the womb without descending in the pelvis more than one-fourth of the distance necessary to produce such a result, if the mouth of the womb itself had not been drawn up into the abdomen. I would like to impress the idea that nature will, and does, at the expiration of the first stage, obliterate, to a great extent, the cervix, drawing it up from between the head of the child and the superior strait, stretching it out to such an extent that it is almost continuous with the vaginal wall, leaving, when on the stretch during a pain, little more than an elevation, or ring, around the inside of the hollow tube constituting the vagina and uterus. Bearing this in mind, it will be seen that the child's head will slip through the superior strait much more easily if you will wait until the uterus has been thoroughly drawn up, than if you apply your forceps before the mouth of the womb has been completely and entirely dilated; and no doubt most of the lacerations of the cervix, which are so common, have been produced either by imploring the patient to "bear down" during the first stage, or by the application of the forceps to the head of the child before the mouth of the womb has passed up to the child's neck. Indeed, the forceps should never be applied to the head of the child while it is covered by the womb, if it can be avoided, and they should always be removed after the head has been brought down to the perineum, except, of course, in those rare instances where puerperal convulsions, or some other grave complication, renders it imperative to make the most rapid delivery possible.

NOTE.—Benjamin's modification of the Simpson forceps is manufactured and sold by J. H. Gemrig & Sons, Phila.

EDITORIAL DEPARTMENT.

PERISCOPE.

Incidents in the Life and Labors of Louis Pasteur.

Dr. Samuel Bell thus writes in the *Medical Age:*

The subject of the following remarks was born in Dôle, France, in 1822. Throughout the greater part of his life he has been laboring for the advancement of science. At an early age he manifested a desire for scientific pursuits. His genius in that direction soon gave him the title of an able experimentalist. At the early age of thirty-two years he was made Dean of the Faculty of Sciences, at Lillel, a town in which one of the principal industries is the manufacture of alcohol from beet root. His investigative genius drifted towards the subject of fermentation. In 1857 he first gave his authoritative views with reference to the germ theory of fermentation, and by crucial experiments and demonstrations proved beyond a doubt the correctness of his statements. His next experiments were made upon wine and beer. After a series of investigations, Pasteur was led to recognize two distinct forms of microscopic life, one of which he termed the ærobies, which require

air, and the other the anærobies, which live without air. Both classes of these organisms conspire to accomplish the great work of keeping up the balance of nature, by giving back to life the material that is essential to its own production.

During the dark days of the supremacy of the commune in France, Pasteur was occupied in studying the little living ferment in beer and wine. Near the conclusion of the national war, he remarked that the "etiology of contagious disease was on the eve of having unexpected light shed upon it." In 1862 his attention was called to the deadly disease which was attacking sheep, cows, horses, and rabbits, and which was communicable to man, known generally under the name of splenic fever. After a careful study of the question, Pasteur affirmed that the living bacilli or micro-organisms which had been before discovered by Davanne and Rayer were the real cause of these terrible diseases. All the foregoing investigations and experiments were but the initial steps to greater and grander achievements. His marvelous career from this date commands our admiration and attention. Whilst he was engaged in his investigations into the nature of splenic fever, his attention was called to a destructive fever among fowls, called "the fowl-cholera." Pasteur soon discovered that a minute microbe was invariably present in the infected fowls, and that he could reproduce the disease at will by introducing these organisms into the blood of the healthy fowls. He also noticed that whenever a drop of liquid containing these microbes was mixed with the food which was given to the healthy fowls, the disease was communicated to them, manifesting itself through the membranes of the intestinal canal. He next found that he could multiply the microbe itself by feeding it artificially in a decoction of fowl-flesh, and that the minutest part of a drop of this artificial cultivation introduced on a needle point into a healthy fowl produced the disease, and severe enough to produce death. His keen investigative discernment now manifested itself to a remarkable degree. It occurred to him, as they were ærobic organisms and subject to the influence of the air, might not the virulence of the contagion be modified by allowing a certain length of time to intervene between the attenuation of the microbe and the inoculation. The attenuation was made, each cultivation was put into a glass flask, plugged with cotton-wool sufficient to prevent the ingress of any floating germ which might be in the atmosphere, and at the same time allowing the entrance of pure filtered air. Another inoculation was made, with the results just as foreseen by the great scientist. The fowls that were inoculated by this kind of virus in a few days became ill and feverish, but no deaths resulted. Another very important fact was established; that after an inoculation of the most deadly virus into fowls previously inoculated by the modified form, not one death ensued, proving the self-protective nature of the disease.

After this important discovery, he still farther prosecuted his studies and investigations with reference to splenic fever, called by the French charbon, by the Russians Siberian pest, and by the Germans milzbrandt. It is a disease which chiefly attacks the lower animals, cows, horses, sheep, and is very deadly and capable of being communicated to man. M. Pasteur stated before the International Medical Congress, which convened in London, in 1881, that France lost animals from charbon annually to the amount of 20,000,000 francs. It was discovered that this disease was also of a non-recurrent type. Did an unfortunate victim ever recover from an attack, immunity from the fatal disease was forever established.

Pasteur discovered that the microbe which produced this disease differed from the others he had studied, in that an attenuated form could not be produced by long exposure to the air. On February 28, 1881, he made the memorable announcement to the Academy of Sciences that he had succeeded in securing a protective vaccine for this most terrible disorder.

It was at once proposed that he should demonstrate the efficacy of this vaccination by a public experiment. Pasteur immediately acquiesced in the suggestion, and it was arranged that fifty sheep should be placed at his disposal, and that twenty-five of these should be subjected to two inoculations at intervals of from twelve to fifteen days, from two vaccines of unequal strength. Some days afterwards these twenty-five sheep, and at the same time the other twenty-five sheep which had not been vaccinated, should be simultaneously inoculated with the virus of virulent splenic fever. Ten cows were also provided, and treated after the same manner. On June 2, more than two hundred people assembled to witness the result. Out of the twenty-five sheep that were not inoculated, twenty-two were dead, and the remaining three dying. The remaining twenty-five which were vaccinated, were well and in good condition. The non-vaccinated cows had large swellings, intense fever, and ano-

rexia; the vaccinated cows were all in good condition. The demand for splenic vaccine became so great that M. Pasteur was obliged to establish a manufactory for splenic fever vaccine a short distance from his laboratory, and at the end of the year had vaccinated 39,346 animals. It was just previous to the above experiment that his daughter made the public statement that "her father would in the near future make some valuable developments in the scientific world." Whatever may be our opinion with reference to many of his previous experiments, the one narrated above has stood the closest criticism, and proved to a demonstration the value of his researches in connection with a very formidable disease. M. Pasteur, in his London address in 1881, stated that the renowned Lister, on reading his publication on milk fermentation in 1857, first received the inspiration which enabled him to mature the most valuable contributions which surgery had received during the present century. Dr. Davarue, who had also labored assiduously, and not without some success, in trying to find the cause of charbon, gave Pasteur the credit of first inspiring him, or suggesting to him ideas which led to his labors in the above direction, from reading his work on butyric fermentation and the vibrio which is characteristic of it—an instance of the evolution of genius. In 1868 a sad event happened to him, which, for a time, threatened his life—an attack of paralysis on one side. In the conviction that he was about to die, he dictated to his wife a note respecting some conclusions which he had arrived at, to be formally communicated to the Academy of Sciences. He said feelingly: "I regret to die. I should like to render more service to my country." Happily for the country he did not die, but he never regained the use of that limb. The French government gives him a pension of 25,000 francs annually, in order to encourage scientific investigations, a precedent which other countries would do well to follow. While many of his deductions are open to candid criticism, yet he has established enough to disarm critics in several directions, and is at the present time gaining the confidence of many of our most conservative minds.

The Rational Treatment of Nasal Catarrh.

Dr. A. G. Hobbs thus writes in the *Southern Med. Record:*

To treat successfully the diseases of the upper respiratory tract, it is necessary that we have a full knowledge of the various means of examining the diseased parts, else our diagnosis will be guess-work, and our treatment as liable if not more so to do harm as to do good. With some physicians there seems to be but one name, and I might add but one treatment, for all diseases of the nose characterized by a discharge. It matters not whether the discharge be caused by a nasal polypus, a sarcomatous tumor, a fibroid, a foreign body, an ulceration, an hypertrophy over the turbinates, or an atrophy of the mucous membrane, it is all called *catarrh*, and is treated in the same manner, by some so-called specific, by means of an anterior or posterior nasal douche, or by the introduction of some irritating powder. These so-called specifics are always irritating and often very painful, so much so that their use cannot be and fortunately is not persevered in.

The practitioner who invariably resorts to this mode of procedure in a routine way, generally knows as little about what is producing the discharge as his unfortunate patient. Is it any wonder, then, that catarrh is regarded as incurable, when it is so universally treated without any discrimination? Almost any medical journal we pick up contains some catarrh remedy vaunted as a *sure cure* without regard to the cause or character of the disease.

Since it is a fact that a large proportion of the communities in which we live suffer with some form of nasal catarrh, does it not seem strange that its pathology is not more generally studied, when the same amount of labor in this direction will give us better results than in almost any other towards an amelioration, and, in most cases, an entire cure of the disease? We have to treat the pathological conditions as we do in other diseases when we reach success. There can be no specific for a nasal discharge that may have so many causes.

If we would proceed rationally then in these diseases, the first thing we should do is to ascertain by a careful examination the cause of the discharge and the condition of the nasal membrane. If caused by a polypus, this must be extracted either with a snare or by the application of chromic, acetic, or nitric acid, or by the thermocautery. If it be caused by a fibroid or sarcomatous tumor, the same means must be pursued, but either will be more difficult to extract than a polypus. If by a foreign body, it must be extracted. If by an ulceration, it must be locally cauterized and constitutionally treated, or both, as the case may demand. If hypertrophic tissue is

found on the turbinates, it must be snared away if large, or scarified if it partakes of the nature of cavernous tissue. All of this should be done with practically no pain by the thorough use of cocaine.

In the meantime, what should be done in these cases, or in others where no tumors are found? Should the anterior nasal douche be used, containing some irritating astringent? Never!—because it does not reach any part of the nasal fossa except the floor, and while it may wash out some of the accumulations contained there, its secondary action of causing the tissues to swell will overbalance the only good it can perform—that of washing the floor of the nose.

Should the posterior nasal douche be used? *Never!* While it can do more good (if effectually used, and not one person in ten can ever learn to effectually use one) than the anterior douche, it may do a great deal more harm by throwing the fluid into the eustachian tube and causing middle ear inflammation.

Then what is to be done when the catarrh is found to be due to an inflammation of the mucous lining of the nose (the result in nearly all cases of a succession of colds), without a polypus, or a tumor, or a foreign body, or an ulceration?

Sprays containing some emollient and non-irritating fluid, such as warmed vaseline, furnish the only rational means of reaching every part of the diseased membrane for the purpose of cleansing and medicating without irritating it. It is necessary that the material used in the spray should be perfectly harmless to the healthy tissues, exert a soothing influence to the diseased tissues, and have a tendency to lessen the inflammation.

These sprays should be applied both posteriorly and anteriorly. After the parts are thoroughly cleansed, any astringent, resolvent, or alterative, such as pinus canadensis, eucalyptol, sandalwood oil, wintergreen oil, pure terebene, or carbolic acid, as the case may demand, may be added to the vaseline spray in small quantities.

It should be remembered, however, that no spray treatment should ever irritate the parts to which it is applied; hence the strength of the medicated spray should be gauged accordingly.

These treatments should be made daily by the physician himself for some weeks, then three times a week, and twice a week, according to the case. In this way alone do I believe that the great majority of the nasal catarrhs can be cured.

As to the constitutional treatment, I do not believe any is necessary except as indicated by the systemic condition. A torpidity of the bowels or kidneys should of course have laxatives or diuretics. A weakened condition of the system will also demand tonics and stimulants, but in most cases no internal medication will be found necessary.

Scarlet Fever and the Puerperal State.

Dr. G. F. Harvey, of Parsons, Kansas, reports to the *Medical Record* the case of a woman who, "on the seventh day after childbirth, got up to have her bed re-made, during which a neighbor's infant was laid upon it; when taken off the child was seen to be covered with a red rash, and it died of scarlet fever during the week. On the following day the patient, having passed a restless night, was found with a temperature of 104° F., dry skin, red strawberry tongue, complaining intensely of headache, smarting of the eyes, and burning pains in the abdomen, limbs, and feet. There was a tendency to delirium, the abdomen was swollen and very tender, the lochia had almost stopped, and had a very offensive ammoniacal odor. Her first child, about two years of age, had been taken sick also through the night, and now presented a clear case of scarlet fever, and in due time desquamated. For about five days the mother's condition was quite critical, large doses of opium being necessary to control the abdominal pains, which were spasmodic in character, and accompanied by an almost constant belching. Recovery took place, there not being any sore throat, rash, desquamation of the skin, or other symptoms of scarlet fever, except 'the tongue' and smarting of the ocular conjunctiva. Since this time the patient has been again delivered normally. I was not present, although called about the second week to treat her for abdominal colic, with eructations similar to those above referred to, and I was told she had had stomache-aches very frequently since, although before her health had been superb. Her first labor was natural. I had acted as counsel at it, in the first stage, during which she had been wrongly instructed to make strong bearing-down effort twenty-four hours before full dilatation occurred. About a month or six weeks after the patient and child were convalescent, the husband, a plasterer, did some work at a house several blocks distant. Precautions had been taken to exclude him from contact with the family. In about three days a little girl came down down with scarlet fever. She had been met outside the house, taken up and kissed, on

the occasion of the first visit of the workman. During the month following six children of this family were attacked by the disease, three of them having severe throat symptoms. The mother, who was very near her confinement, nursed them all through, and while the last three were still in bed, was delivered, a face presentation making a tedious labor, but without any hemorrhage until the placenta was delivered by expression half an hour or more afterward. There was no manual interference in the delivery after the discovery of what was thought to be vertex presentation early in the case—and, contrary to custom, the same with the placenta—so it is very probable there was no abrasion of the parts, as there was no appearance of blood on the child. A point is made of this, as it is thought that micro-organisms do not commonly affect the parts of parturients unless there is some solution of continuity for them to nestle and propagate in. The patient made a good recovery, and resumed her duties on the ninth day. The babe took scarlet fever on the fifteenth or sixteenth day, had sore throat, swelled neck, fever, general rash, and desquamated skin and hair. Scarlet fever had been prevalent about this time, and I had learned of two ladies dying of puerperal fever in our community—one, a primipara, who in the first week had inhaled air that blew over a lawn on which was spread the bedding of a child that had recently died of this fever, and the other was exposed in some way unknown to me. I would gather from these observations that antiseptic precautions are more especially necessary, after instrumental and primiparal labors, during the prevalence of infectious diseases, while it is not of importance in cases which suffer no lacerations of the genitals."

Prolonged Somnolence.

The Paris correspondent of the *Brit. Med. Jour.* (September 4) thus writes:

Eudoxie Hedouin, the patient at the Salpêtrière, who has just woke up after eighteen days' sleep, entered the Salpêtriére Hospital in 1862. Her mother died from cancer of the stomach. During six years she was subject to epileptic attacks, but these occurred after the birth of Eudoxie. This patient cannot give any information concerning her childhood, whether or not she had convulsions; all she remembers is, that she cried out and laughed without knowing the cause. When she was eighteen years of age, epileptic attacks came on, under what circumstances is not known; at the age of 19 she was treated for gastritis; at 21, she miscarried at the fifth month of pregnancy. During eight months she suffered from frequent uterine hemorrhage. During pregnancy she suffered greatly from sickness, but her epileptic fits were not modified. After a series of these attacks, which occurred when she was 22 years old, she became paralytic, and remains so. She first entered the Salpêtrière to be treated for paralysis. Her lower limbs were perfectly rigid; she suffered acute pain in the knees, and the left knee was considerably swollen; she was treated by cupping. She then went from hospital to hospital, and in 1865 was attacked by cholera. In 1886, she again entered the Salpêtrière Hospital. She had grown very stout; the abdomen was greatly enlarged; she scarcely ate anything. On the left side of the abdomen there was dulness on percussion. Examination produced pain, hence it was impossible to ascertain the symptoms. She could move her arms freely, but the lower limbs were paralyzed. On May 7th, 1875, she fell asleep, after taking a purgative. The face was calm; the eyelids frequently quivered, and did not always close over the eyeball. When her head was shaken, she awoke, and said she did not dream. On the afternoon of the same day, she slept a long time; on the 8th she frequently fell asleep, and was easily awoke. On the 12th, her sleep persisted, and continued until the 27th. The following day, the 28th, she made a meal, afterwards laughed violently, and then became delirious. The next morning (29th), her upper and lower limbs were rigid, but the feet were not. Last January she slept during fifty days; she has now just awoke from a sleep of eighteen days. During her attack of somnolence Dr. Voisin placed on her skin an emetic, well wrapped up, without saying anything No effect followed. This was removed, and a piece of paper carefully folded and perfectly empty, was next placed on the patient's skin, Dr. Volsin remarking that "she would certainly vomit." Ten minutes afterwards the patient was sick, which proved that during her sleep she heard. The day after she awoke she was given an empty glass, which she was told contained champagne, and a piece of aloes instead of sugar. Two or three times she simulated drinking from the glass, and then swallowed the supposed piece of sugar, which provoked a slight grimace. She showed all the symptoms of drunkenness. Since she awoke the last time, she eats, drinks, sleeps, and cuts her nails, but her mental condition is not normal. She is now 51 years of age.

The Treatment of Tape-Worm.

Dr. James T. Whittaker thus writes in the *Med. News:*

These remedies may be ranked in efficacy as follows:

1. The bark of the pomegranate root, of which three ounces should be macerated in twelve ounces of water for twelve to twenty-four hours, to be then reduced one-half under gentle heat. The whole quantity is to be taken in divided doses in the course of an hour. Pomegranate root remains the most effective of all anthelmintics, and would long since have excluded all others did it not at times produce nausea, vomiting, and colicky pains. To avoid the first of these evils, Bettelheim suggests the introduction of the infusion into the stomach by means of the stomach-pump, and to obviate all of them, Feraud recommends pelletierin, an active alkaloid of the root named in honor of the discoverer of quinine. One to two drachms of the infusion of senna is to be taken on the morning following a day of fasting, and in the course of an hour one-fourth to one-half of a grain of the tannate of pelletierin suspended in water. Half an hour later the same dose is repeated, to be followed in an additional half hour with a tablespoonful of castor oil, the patient remaining meanwhile quiet in bed, to avoid disturbance of the stomach. In one instance, twelve beef tapeworms were expelled at once in this way.

2. Turpentine is a powerful tæniacide, but the use of it is liable to cause headache, pain in the stomach, fever, and strangury. These effects are, however, much less frequent after large than small doses. Hence the dose for an adult should be never less than one to two ounces, for a child one drachm to one ounce, according to age. It may be administered in emulsion with white of egg or be briskly stirred in half a glass of milk and swallowed rapidly. Should it fail to act as a cathartic, it should be followed with a dose of castor oil.

3. Male fern, the ethereal extract, two drachms in four or five gelatine capsules, of which one may be swallowed every five minutes with the aid of a cup of coffee. A dose of castor oil with brandy should follow the capsules in the course of half an hour.

4. Kousso, koussin, pumpkin seeds, santonin, kamala, carbolic acid, zinc, and other parasiticides of less value.

Every attempt at treatment being a forcible intervention, only such individuals should be subjected to it as are known to be affected. The mere statement of a patient is not sufficient proof, and cases of tæniaphobia do not justify it, on so-called psychological grounds, because failures only aggravate the condition as a rule. Pregnancy, advanced age, debility from any cause, are contraindications to all treatment. The physician must be awake to cases of deception. Heller reports the case of a child finally debilitated by repeated treatment because of the continued exhibition of segments of the worm, when, upon closer examination, it was discovered that the fragments did not come from the child at all, but from a lazy nurse, who made a convenience of the child's stool-chair.

Curable Hypertrophic Cervical Pachymeningitis.

Dr. Edgard Hertz briefly considers the somewhat meagre literature of the subject, and then reports two cases coming under his own observation. In addition, he details two cases reported by O. Berger (*Deut. Med. Wochenschrift*, 1878), one by Féré (*Progres Medical*, 1883), one by Joffroy (*Arch. Gen. de Med.*, 1876), and one by Burtin (*These de Paris*, 1878). From these observations he feels justified in formulating the following conclusions:

1. That the disease is caused in the majority of instances by exposure to cold, living in damp dwellings, and prolonged exposure to currents of air.

2. That an analysis of the symptoms confirms the division of the disease into three periods: pains, paralysis and atrophy. For the latter we may advantageously substitute the term period of trophic disturbance, as in fact a veritable atrophy never exists, the muscles preserving the normal volume.

3. That there is a great excess in the quantity of urea excreted, in one case amounting to seventy-six grammes per litre. Improvement is accompanied by a fall in the proportions of urea in the urine.

4. That the disturbances of the sexual functions follow the same course, at first true satyriasis exists, followed by absolute but temporary impotency.

5. That the course of the disease justifies the title of the paper. Cervical pachymeningitis *is curable,* rarely in the first period of the disease, but during the period of paralysis and trophic changes.

6. That from the observations of Joffroy, Féré and Burtin, sensible amelioration of the symptoms may be expected in about eighteen months. Prognosis is, however, unfavorable when the disease affects the lower extremities; when the bladder and rectum are affected, or when the deformity of *main*

en griffe exists, with wasting of the muscles of the shoulder and the flexors of the forearm.

7. That the prognosis should be favorable in the largest number of cases, and that recovery does not take place progressively, but by sudden improvements followed by temporary relapses, which necessitate continuous surveillance and moderate and prudent interference.

8. That the treatment in the painful period should consist in the employment of anodynes, chloral or morphine subcutaneously, and counter-irritants should be freely applied to the cervical region, particularly scarifications and the actual cautery. Prolonged hot baths are of great service. Electricity exercises a favorable influence over the trophic disturbances. The salicylate of soda is of great value in many cases, as the disease is frequently of rheumatic origin.

Paracentesis Pericardii.

Dr. Samuel Westray Battle thus writes in the *N. C. Medical Journal:*

Samuel Reynolds, brick mason, white, aged 60, native of Georgia, admitted to Mission Hospital, Asheville, N. C., July 21, 1886. Patient is of good physique, fairly well nourished. Gives vague history of rheumatism several years ago. He had been ill for a month, his health generally having failed him. He complains of ill-defined pains in left half of trunk from shoulder to hip, front and rear, but there are no subjective symptoms pointing to the heart or its envelope. Upon inspection the face is observed to be anxious, the respiration hurried and superficial. Closer examination elicits a much enlarged area of cardiac dullness; heart sounds muffled, distant and feeble; pulse intermittent and barely perceptible at the wrist, at times not at all so; hands and feet cold, and a clammy sweat is upon the brow and extremities. Upon consultation with Drs. McGill and W. D. Hilliard, the diagnosis of effusion into the cavity of the pericardium, with imminent heart paralysis, is confirmed, and it is decided to aspirate, and that right quickly. Consent of patient being gained, a valvular incision is made in the skin, in the fifth intercostal space, at a point corresponding to the normal apex beat, this being about the centre of the pyriform tumor made by the distended pericardial sac; a medium-sized aspirating needle, attached to the exhausted graduate, is introduced into the tissues and the stop-cock at once opened, that the fluid may start immediately upon the needle reaching the sac. Straw-colored fluid, to the amount of 17¾ ounces, is withdrawn with the most gratifying results. The pulse has returned to the wrist, the heart-sounds, though still muffled, are easily distinguishable the one from the other; the breathing is easier; the whole aspect of the man has changed, and Mors, at least for the nonce, has relaxed his grip. A glass of whisky and water is ordered, and the following, to be commenced at once:

℞. Digitalis tincturæ, ℥j.
Jaborand. ext. fl.,
Tongaline, āā ℥j.
Sig.—Teaspoonful every four hours.

August 12.—Three weeks have elapsed, and there are as yet no signs of reaccumulation of fluid in the pericardial sac. By noon of the day following the exhibition of digitalis, jaborandi and tongaline, nausea and diaphoresis were produced, and the medicine was given less frequently. Two days later, tincture digitalis and fluid extract of stigmata maïdis replaced other medicine, and these, in conjunction, are still continued. The heart-sounds have cleared, but are not normal, some degenerative change in the valves and walls having been probably taking place for some time.

The first sound has lost its booming quality, having become short and valvular like the second, and is now and then intermittent; no indefinable murmurs. Patient is comfortable, sleeps well, breathes easily and naturally, eats well, and takes daily exercise without discomfort. In fine, there seems no reason why he should not regain his former moderately good health.

Intraperitoneal Injection in Hemorrhage.

Dr. Rutgers, of Rotterdam, publishes, in the *Weekblad van het Nederlandsch Tijdschrift voor Geneeskunde,* a case of dangerous post-partum hemorrhage, which was attended by a midwife, and not seen by himself till four hours after delivery, when the woman was found to be pallid, cold, and almost unconscious. The external hemorrhage had ceased, but coagula were filling the vagina, and internal hemorrhage was still going on. A subcutaneous injection of Wernich's extract of ergotine was given, and the uterus manipulated externally. These measures immediately arrested the hemorrhage, but did not improve the patient's condition of collapse. A little water was swallowed, but immediately vomited. An hour later, an injection of ether was given in the left arm, and some port wine was swallowed

and retained. The condition then improved, and the pulse became perceptible. A saline solution of six grammes of chloride of sodium and 0.3 gramme of hydrate of soda, in a litre of water, was prepared, and heated to the temperature of the body; fifty grammes were injected by means of an aspirator needle, into the right thigh, and both legs were raised so as to cause as much autotransfusion as possible. No effect, however, was produced on the pulse or general condition. It was then proposed to attempt an intravenous injection of the saline fluid; but no distension of the veins of the arm could be obtained by compressing the upper part of the arm. Dr. Rutgers therefore introduced the solution into the peritoneal cavity, in the hope that it would be taken up by the vessels there, and so pass into the circulation. Half a litre was thus injected with great care, and very shortly afterwards the pulse improved, and the patient was able to speak. After this she did well. She complained the next day of pain in the abdomen, and the temperature was for three days below normal. The writer thinks that this case may show the possibility of intraperitoneal injections in desperate cases, and that such injections may not only be well borne, but may have a very rapid and satisfactory effect. He suggests, too, that perhaps this proceeding may be found of value in the collapse of cholera.

Tubercular Ulcer of the Tongue in a Woman; Removal of the Front Portion, followed by Complete Cessation of the Local Pain.

Mr. Vincent Jackson thus writes in the *Lancet:*

Rachel L., aged thirty-seven, an in-patient of the hospital, was transferred from Dr. Malet's wards to those of Mr. Jackson on account of a very painful ulcer of the point of the tongue. The woman had been married for several years, but had never been pregnant, and her family history showed that her youngest sister died of pulmonary consumption, a disease from which she was suffering in the upper portion of each lung. She states that six months ago she perceived a hard pimple on the front "edge" of the tongue, which was not preceded by an injury or by any irritation in the front teeth, which are well formed and free from caries. Three months afterwards an ulcer formed and has enlarged, and on account of the great pain which eating and the various movements of the tongue caused, she was anxious, as all local applications had failed to give relief, for something more to be done.

On admission, the tip of the tongue was seen to be occupied by a shallow ulcer, oval in shape, measuring half an inch across and a quarter of an inch from above downwards. The floor had a greyish look, and was uneven and nodular, the edges being slightly undermined, but there was no surrounding induration, separate nodules, minute ulcers, or enlarged glands.

April 22. The patient being in a semi-recumbent position on a couch, ether was administered, and the mouth being well opened by a gag worked from the left side, the tongue was pulled out and grasped by a pair of long-bladed forceps about an inch from the tip, and about three-quarters of an inch of this portion of the tongue was cut away with scissors. The mucous membrane of the two surfaces was united by ten points of interrupted suture of very fine silk. The tongue being released, and no hemorrhage ensuing, the mouth was closed, and the patient removed.

26th. All the sutures were removed.

May 4. Patient discharged, wound quite healed. The operation has been followed by a complete cessation of all the distressing symptoms complained of previously.

Tolerance of Hydrate of Chloral and Bromide of Potassium.

Dr. L. G. Taylor thus writes in the *Kansas City Med. Record:*

The case reported below shows a rather remarkable tolerance of chloral hydrate and bromide of potassium:

A certain well known gentleman of this city is subject to very severe attacks of headache of a markedly congestive character, recurring at irregular intervals of a week or a month or more, otherwise being particularly healthy.

I was called to him on the night of July 17, 1886, at 11 o'clock, and found the following state of affairs: During the last previous attack he had obtained from a physician this prescription:

℞.	Pot. brom.,	℥ ss.
	Chloral hyd.,	℥ ij.
	Elixir simp.,	℥ ij.

M. S.—Teaspoonful every hour until relieved.

On the evening of July 17, at 8 o'clock, while suffering with a severe headache, he took what was left of the original bottle—about two teaspoonfuls—and sending to the druggist had the prescription refilled with double quantities—a four-ounce mixture. On receiving it, being rendered unconscious

by excessive pain, he took two doses in quick succession, without care as to quantity, the last dose being taken at 9 p. m. I found the bottle but little over half full, and none having been spilled, he must have taken from the two bottles not less than two ounces of the mixture—that is ʒss. of the potassium bromide and ʒij. of the chloral.

The patient was in a profound sleep, into which he had fallen shortly after taking the last dose. His pulse was 74, full and regular; respiration 17, and easy; temperature normal; the pupils slightly contracted. On trying to arouse him, he muttered some unintelligible words, turned over, and lay quiet again. I gave him a hypodermic of ♏iij fluid extract of belladonna. At the prick of the needle he wakened and objected, but soon consented and went to sleep again. There being no alarming symptoms, I left at 11:30 p. m., and returned at 11 a. m. On my return I found him still sleeping, but easily aroused and in good condition, though he said he felt quite weak and did not remember anything since nine o'clock the night before. He had slept an apparently normal sleep of fourteen hours.

The Removal of Hemorrhoids Rendered Painless by the Injection of Cocaine.

Dr. J. Prince Stullard thus writes in the *Brit. Med. Jour.*:

The two following cases may prove interesting, as showing the usefulness of cocaine as a local anæsthetic in operating on hemorrhoids.

Case 1. A gentleman consulted me on June 12, 1886, for a painful swelling, saying that he thought that "his seat had come down." On examination, I found a large venous pile, tense and shining, and tending to ulceration, the base of which sprang from just within the margin of the sphincter ani. With difficulty and pain, it was reduced; but, as it descended on the following day, it was decided that it would be best to tie it. The patient was a very sensitive man, and asked that chloroform might be given to him; but, thinking it was a suitable case, I decided to try the effects of cocaine. Five drops of a ten per cent. solution of hydrochlorate of cocaine were injected, by means of a hypodermic syringe, into each side of the base of the hemorrhoid; and, after waiting five minutes, the tumor was seized with a vulsellum, transfixed with a double-threaded needle, and tied in the usual manner. A morphine suppository was placed in the rectum, and, from the commencement of the operation up to complete recovery, a period of eight days, the patient did not experience the slightest pain.

Case 2. On June 17, a young pregnant woman consulted me for a large venous pile, commencing to ulcerate, and occupying the same position as in the preceding case. The same number of drops were injected, and the hæmorrhoid was tied. She experienced no pain during the operation, which was attended by no evil consequences.

In both the above cases, no toxic effects were produced from the use of cocaine. The solution used had been kept for three months, and contained one grain of hydrochlorate of cocaine in a drachm.

Remarks.—By means of cocaine, operations for the relief of hæmorrhoids can be rendered painless, but the effect of the drug soon passes off; and, to ensure absolute freedom from pain, it is necessary to follow it up with morphine, administered in one of its many forms. By using cocaine as above described, the operation is rendered much easier, and can be accomplished by the surgeon single-handed without the help of an assistant, who is indispensable when a general anæsthetic is employed.

Ptomaines.

The following occurs in the course of an article in *Gaillard's Medical Journal* for September, by Dr. L. B. Anderson:

From the foregoing summary we learn:

1. That in the decomposition of animal tissues and juices there are formed certain alkaloids, designated by Selmi "ptomaines," because first discovered in a putrefying dead body.

2. That these ptomaines have been discovered in minute quantities in normal human saliva and urine, and in large quantities in snake poison.

3. That they are found in the secretions of patients laboring under typhus, jaundice, diabetes, ileus, pneumonia, peritonitis, and other morbid states.

4. That they are found likewise in various decomposing tissues and fluids, such as brain, muscle, nerve, liver, stomach, bowels, and all decomposing albuminoid matters, as well as the culture-fluid of bacilli.

5. That some are amorphous, some crystalline, some oily, some very soluble, some very insoluble, some liquid and some gaseous, some bitter and nauseous, some sweet and palatable, some aromatic and agreeable, and others extremely fetid and stinking; some innocuous, and others virulently poisonous.

6. That different qualities of ptomaines

are produced by the same agent in the various stages of the putrefactive process—one being decomposed by newly generated bases, and their constituents uniting to form other and different compounds; while different bodies produce their own peculiar and characteristic ptomaines.

7. That the physiological action of almost all known vegetable alkaloids finds a striking similitude in the effects of ptomaines—some acting on the nervous centres, paralyzing the vaso-motor nerves; others exciting those centres, increasing the action of the heart and arteries; some acting on the muscular system, suspending the peristaltic action of the intestines, while others inordinately excite the contractile fibres, producing violent emesis and diarrhœa; some exciting the secretion, causing the saliva, urine, bile, and mucus to flow more freely, while others suspend those functions, causing dryness and fever; some producing coma, and others wild and wakeful delirium, etc., etc.

Oil of Eucalyptus in Malarial Disease.

Dr. J. H. Musser (*Ther. Gaz.*, June, 1886) gives a critical analysis of the results he has obtained with eucalyptus in the various forms of malarial poisoning. Great care was exercised in diagnosis, and twenty-eight patients were selected for treatment. Of these, nine were cured, ten not cured, five were relieved, but other drugs were used in addition, and five did not report a second time. Analyzing the nine cured cases, one was of quotidian type, five were tertian, one was quartan, and two were irregular. The disease was acute in five, chronic in four. The cases were under observation from ten days to six months. All the attacks developed in the usual malarial season, and seven of the patients resided in a positively well-known malarious locality. The drug was administered in forty-four other cases in which the symptoms showed periodicity and consisted in irregular febrile invasions, gastro-intestinal disorder, and neuralgias. Only eighteen of these cases remained under observation long enough to be of any statistical value. Fourteen patients were relieved and four were not relieved. The former were under observation from five days to a year.

The oil, which is quite distasteful, may be administered in capsules, in emulsion, or in glycerin. Most of the author's patients took it on a lump of sugar. Ten drops are usually given to adults, three or four times daily. The author thinks smaller doses (gtt. iij–v), repeated oftener, would prove more beneficial.

He draws the following conclusions:

1. Oil of eucalyptus is of decided value in about one-third of all the cases of intermitting malarial fever.

2. It has no specific value in any one type of the disease.

3. The longer the duration of the disease, the less liable it is to do good.

4. Relapses are not prevented by it.

5. Its influence on the spleen has not been demonstrated.

6. A dose of ten drops four times daily is a sufficient dose, but five drops every three hours would possibly be of greater value.

7. Good results are not attained so quickly as by large doses of quinine, but a good effect should be observed within five days at least.

Mary-thistle (Carduus Marianus).

Mary-thistle, Steck-kornchen, Chardon-Marie (Carduus Marianus), a syngenesious biennial, formerly enjoyed a considerable reputation. In Germany the leaves of this plant are used against dysentery and hemorrhage, and the seeds in the treatment of spleen and liver enlargement. Tripier had found it of value in the treatment of female diseases. The discredit and disuse into which the Mary-thistle had fallen was difficult to explain, since there was indubitable evidence that it had decided therapeutic virtues.

There was no longer any idea of employing the leaves and flowers, whose chief constituent was tannin. The seeds do not contain tannin, but 25 per cent. of a fixed oil, separated by benzine, but slightly soluble in strong alcohol and still less in 60 per cent. alcohol. It deposits, from time to time, crystals whose reaction is neither that of an acid, an alkali, nor a glucoside. On treating the seeds with 60 per cent. alcohol, a liquor results, which yields on evaporation a gummy, resinous extract in proportion of 12 per cent. of the seeds employed.

Dr. Tripier prescribes ten to forty drops of the tincture. He also uses about one-fifth of a grain of the alcoholic extract, combined with three-sevenths of a grain of aloes against constipation.

These pills do not congest the bowel, and hence do not have the tendency which aloes alone has, of producing piles. Aloes alone in the quantity given, would be useless against constipation, and its action in the present instance is due to the Mary-thistle

extract which stimulates the liver, and the excessive secretion of bile therefrom resulting produces the desired effect. Marythistle seeds are hence of value in liver and spleen diseases and their consequences, and hence have properties similar to those of burdock.

Stilling the Heart by Will-Power.

The *American Practitioner and News* says:

It has every now and then been mentioned as one of the curiosities of physiology, that instances have been noted of men capable of stilling the heart by the power of the will.

As in nearly all other manifestations of peculiar qualities, it will likely be found that this is only an exaggeration of a quality or faculty possessed in some degree as a normal attribute by the race in common. It may be, however, that, in the most remarkable of these cases, the fibres of the spinal accessory, instead of passing off to the superior and inferior laryngeal muscles, pass on to the heart, and give the individuals so organized an unusual voluntary control of the organ. Most persons control the heart's action to whatever degree they are able, either indirectly or unconsciously. It can be done, to a large extent, through the breathing. By taking full breath deliberately, we may often calm an excited heart. In some way, which we shall not attempt to explain, an inhibitory action is exerted over the heart-beat. A continuous monotony of sound or touch will do it. Every one strokes the frightened horse to quiet him, and Poe had got hold of a physiological truth when he wrote—

> "To still the beating of my heart, I stood repeating."

Some persons can also exercise an inhibitory control over the heart-beat, in the presence or prospect of danger, by visualizing in imagination the worst the situation may bring, and in this supplement courage to a marvelous degree. Indeed, the relation of this inhibitory control of the heart to the manifestation of courage is a question well worthy of critical examination.

The Hypodermatic Administration of Morphia for Autumnal Catarrh.

Dr. Wm. Moss thus writes to the *Medical News:*

In the *American Journal of the Medical Sciences* for January, 1873, I called attention to the hypodermatic administration of morphia for autumnal catarrh. Experience has confirmed the efficacy of this treatment in relieving the paroxysms of this disease, and in moderating the severity of its annually recurring attacks. I venture to report a typical case, though unfinished, because the season is still at its height, and the treatment is available to those practitioners who have not the opportunity to use local means for the radical cure of this distressing ailment.

September 2, 1886, Mrs. A., æt. 30; disease dates back many years; attack began August 10, several days earlier than usual; went to the seashore for a fortnight, during which time the severity of the symptoms diminished; returned on the 30th, with immediate bad results.

Present condition: Violent sneezing, eyes and nose itching, swollen, and streaming; incessant wheezing cough during the day; at night, severe asthma, necessitating the upright position, and entirely preventing sleep. One-fourth grain of morphia sulph., hypodermatically, gave instant and entire relief, which lasted nearly forty-eight hours. This was repeated on the 4th, 6th, 8th, 10th and 11th, with like result (on the last date sooner, on account of the conjunctival irritation). I shall probably be able during the remainder of the period to keep the attack under control, with half-weekly injections. I have not in this, and other cases, obtained relief by the local application of a six per cent. solution of cocaine hydrochlorate.

Daturine.

Dr. E. L. Shurley thus writes in the *N. Y. Med. Jour.:*

From the known value of stramonium as an anti-spasmodic, and its especial utility in the relief of spasmodic asthma, I was led to give this alkaloid a thorough trial as a topical remedy in affections of this sort.

I have notes of twenty-three cases subjected to experiment, as follows: 1, bronchial asthma; 1, spasmodic asthma; 2, periodic laryngeal congestion; 3, hay-fever; 1, chronic bronchitis (bronchorrhœa); 3, hysterical pharyngeal catarrh; 5, influenza; 1, laryngismus (with ovarian disease); 2, chronic naso-pharyngeal catarrh; 2, acute coryza; 2, chronic laryngitis.

The dose varied from $\frac{1}{100}$ to $\frac{1}{50}$ of a grain, and in some of the cases was repeated two, three, or four times a day; in each case, when the dose was large enough or frequently enough repeated, there appeared to the patient sooner or later the characteristic sensation of dryness of the fauces, etc. The

patients with asthma were not sensibly affected by the treatment; two of those with hay fever were very much benefited by the applications if repeated often enough (it was used in the form of spray), but the trouble was not arrested; three of those with influenza were decidedly relieved by three applications daily of a spray ($\frac{1}{100}$ of a grain), while the two others were not at all relieved. The neurotic cases were only relieved by a diminution of secretion, which, however, lasted but a few hours, necessitating a repetition of the dose. In the other cases I could observe no particular effects.

A Case of General Neuritis—Cure.

Dr. Archinard thus writes in the *New Orleans M. and S. Jour.:*

Bernard Underhill, aged 35 years, born in New Brunswick, was admitted to the Charity Hospital, January 11, 1886, suffering with malarial intermittent fever; no history of nervous disease in his family; his habits are good; he has never had syphilis. On day of admission he was taken to bath-room and while in the bath-tub the hot water was turned on and his back scalded. The burn was superficial, and extended on left side from the scapula to the crest of ilium. He was taken to a surgical ward, where he remained until the latter part of March, when he was transferred to the nervous disease ward, when the following history was recorded, on April 2, 1886:

From the time of the accident related above, to date, patient has never left his bed, first, on account of his burn and fever, and then on account of a paralysis which had gradually begun in the upper extremities and then involved the lower extremities. This paralysis, which began towards the latter part of February, attacked first the right hand and arm, and was accompanied by feelings of numbness, burning, and formication; in a few days extended to the left arm and hand, and by the end of March had involved the two legs. Upon examination, marked paresis with flabbiness of the muscles was noticed, feeling of formication and burning in affected parts were complained of. Tactile sensation and sensation to pain were present, though much retarded; the muscular sense almost lost; incoördination well-marked; no atrophy of muscles; absence of the tendon reflexes; bladder and rectum unaffected; patient has a slight evening fever, intermitting in the morning—this is easily subdued by a few doses of quinia; mind clear; no tenderness over spine upon percussion.

By the combined use of electricity, the faradic current, to which the muscles answered but feebly in the beginning, and a mixture composed of iodide and bromide of potassium, grains vijss, the patient gradually improved, and in five or six weeks was perfectly well, assisting the nurse in the ward.

Phimosis with Exaggerated Symptoms.

Dr. T. M. Holmes thus writes in the *Atlanta Med. and Surg. Jour.* for October:

Some months ago I was called to see a mulatto boy about five years of age, who had been suffering for several days from profuse diarrhœal discharges and frequent micturition. He was very much reduced in flesh; his features were pinched, and his skin was dry and harsh. His eyes were of a smoky hue, and he was almost blind. He also had a papular eruption from the crown of his head to the soles of his feet, with a serous discharge not unlike that of eczema. There was more or less pain in the region of the bladder all the while, which was greatly intensified by the accumulation of a small amount of urine in this viscus. When this occurred, he would run the floor, compressing the abdomen with his hands, and cry in such a manner as to enlist the sympathy of all lookers on. He had been losing his vision for several weeks, and growing very nervous.

What could be the exciting cause of this amaurosis, this diseased skin and nervous phenomena? I sought to discover it, which resulted in finding an almost comple phimosis and partially closed meatus.

The diarrhœa was successfully treated, but with no abatement of the other symptoms. It was evident to my mind that the patient was suffering from a severe nervous irritability, the result of the phimosis, and a slow uræmic poisoning, the solid constituents of the urine having been reabsorbed from the retained urine in the bladder. I first sought to relieve the patient by dilatation, which failed to give the necessary relief on account of the condition of the meatus. I therefore performed circumcision, with the assistance of Mr. George Glover. The result was a complete relief, and a disappearance of all the above symptoms. The boy is now in fine health.

Nitric Acid in Testing for Albumin.

Dr. E. H. Trowbridge (*Medical News*, August 28, 1886), in a note on "A Simple Method of Adding Nitric Acid to Urine in Testing for Albumin," says: We must bear

in mind that the specific gravity of normal urine ranges from 1.015 to 1.022, though some authors place it as low as 1.005 and as high as 1.030. Now the specific gravity of nitric acid (U. S. P.) is 1.420, and dilute nitric acid (U. S. P.) is 1.059, each being greater than that of normal urine. To test the urine for albumin, pour into a test-tube of medium size enough urine so that there shall be a column 2 or 2⅓ centimetres in height; then with a pipette or small tube take up a column of nitric acid 3½ centimetres in height, or, in general, let the column of nitric acid be a little higher than the column of urine (so better to notice the displacement of the fluids). With the finger firmly pressed against the upper end of the pipette or tube, pass the latter to the bottom of the column of urine, still keeping the finger pressed against the upper end; the fluids will mix according to the force of their specific gravity—*i. e.*, the nitric acid will gradually flow to the bottom of the test-tube, and the urine will rise in the tube to the height at which was the nitric acid. By this method we can more easily and more clearly notice any turbidity which may be formed, and without any agitation of the fluids. The same method can be followed in using acetic acid (U. S. P.), which has a specific gravity of 1.048, or the glacial acetic acid, which has a specific gravity of 1.056–1.058.

Case of Operation in Hydatid Disease of tho Liver.

Dr. E. Hooper May thus writes in the *Brit. Med. Jour.:*

Mrs. C., the wife of a sea-captain, observed an enlargement of the right side, in the region of the liver. On examination, the bulging was found to be very considerable, so as quite to alter the symmetry of the figure. Under the impression that it was a hydatid cyst, the needle of a hypodermic syringe was introduced, and some clear non-albuminous fluid drawn off, the operation being followed by the usual appearance of some spots of urticaria.

On January 12, 1883, an incision about two inches long was made in the most prominent part of the swelling, through the integument, and down to the cyst. This was packed with iodoform gauze, and was dressed over this with carbolic gauze.

On January 19 the cyst was opened, about a pint of fluid, with a good deal of blood, escaping. A tube was placed in the cyst, and a dressing of carbolic gauze laid over it. The operation was followed by another eruption of urticaria. Both operations and the subsequent dressings were conducted under the carbolic spray. The cyst gradually shrank; and, in the beginning of May, the patient was able to accompany her husband upon a voyage; but the wound did not perfectly heal till the middle of June. It may be worthy of remark that the lady was accustomed to fondle a lap-dog.

Elixir Iron Pyrophosphate, Strychnine, and Quinine.

It is prepared by Mr. E. M. Nadal Wilson (Proc. N. C. Phar. Assoc.) as follows:

℞.	Quinine sulphate,	135 grains.
	Iron pyrophosphate,	256 "
	Strychnine,	2 "
	Alcohol enough to make	4 ounces.
	Dilute sulph. acid sufficient,	
	Aqua ammonia (strong),	½ "
	Water sufficient.	
	Simple elixir sufficient.	

The quinine is dissolved in a pint of water by aid of the dilute sulphuric acid, and when perfectly dissolved it is precipitated with the aqua ammonia mixed with a quart of water. This precipitate is placed on a filter and washed until traces of ammonia have disappeared. The precipitate is then allowed to drain for some time, but is not permitted to draw. By pouring the alcohol on the precipitate with care, all the quinine is dissolved, after which the strychnine is gradually added and stirred, until thoroughly disssolved. To the resulting solution enough simple elixir is added to make eight ounces. The iron is dissolved in enough simple elixir to make eight ounces. The iron and quinine solutions are then mixed and the result filtered, if necessary. The finished elixir will be of an amber color.

Erythanthema Syphiliticum.

Dr. Edward Bennet Bronson thus concludes a paper in the *Med. Record*, September 4:

From the above considerations I draw the following inferences:

1. That certain forms of erythanthema arising in the course of syphilis may be regarded as products of the latter disease; more especially when they coincide with or are directly followed by an outbreak of typical syphilitic manifestations.

2. That in view of their resemblance to simple angioneurotic or neuritic affections of the skin, it is probable that they also correspond to the latter in their mode of origin; and, while doubtless due primarily to the syphilis, they are not pathognomonic of the

latter disease, and probably not equivalent etiologically to true syphilodermata.

3. And, finally, that the syphilitic erythanthema may, through reflex irritation and in the same manner as the local traumatism, become the seat of a characteristic syphilitic infiltration.

The Diuretic Action of Mercury.

Dr. F. Spiller Locke thus writes in the *Practitioner* for September:

It has long been empirically known that the action of digitalis and squill as diuretics is greatly assisted by the addition to them of a little mercury, and lately calomel alone has been greatly lauded as a diuretic.* The part played by the mercury has never been satisfactorily explained, but the recent work of Noël-Paton† on the connection between bile secretion and the formation of urea seems to have furnished the required clue. Noël-Paton has investigated the action of those drugs known to be powerful hepatic stimulants (from the experiments of Rutherford and others), and the amounts of urea, uric acid, and water excreted by the kidneys of the animal (dog) under observation, and has found that uniformly a direct relation can be traced between the activity of a drug as a hepatic stimulant, and its activity in causing an increased formation and excretion of the most important nitrogenous waste-products. The administration, for example, of perchloride of mercury to a dog in a state of nitrogenous equilibrium, caused a marked increase in the amounts of urea, uric acid, and water, excreted by the animal.‡

The fact that drugs which cause an increased formation of bile also cause an increased formation of urea is of great physiological interest, and gives new ground for the belief, widely held by physiologists, that the liver is the great seat of the formation of urea. The bearing of this fact on the clinical use of mercury as a diuretic is evident. Rutherford has proved that mercuric salts cause a greatly increased formation of bile; this phenomenon is, in all probability, only "the outward and visible sign" of some more fundamental action of the metal, one other result of which is the increased production of urea: it may be mentioned that, according to Noël-Paton, this fundamental action is the destruction of red blood corpuscles.

Now it is well known that an increased quantity of urea in the blood acts as a powerful diuretic. In the frog, if the excretion of urine be stopped by ligature of the renal arteries, the injection of urea into the blood at once causes the excretion to commence afresh (Nussbaum, Adami). In the dog, if, by division of the medulla, the excretion of urine be stopped through lowering of the general blood-pressure, and then urea be injected, the flow of urine recommences (Ustimowitsch). It has been shown, by the method of transfusion, that the addition of urea to the blood transfused causes an increase in the amount of blood flowing through the kidney in a given time, the pressure by which the circulation is carried on remaining constant (Abeles). There is thus abundance of experimental evidence for the powerful diuretic action of urea, and the good effects derived from the use of mercury in combination with digitalis and squill are readily explained by its action on some metabolic process, one outcome of which is the secretion of bile, and another the formation of urea.

In a recent paper, Jendrássik (*loc. cit.; Practitioner*, xxxvii., 45, 211,) has described more fully the results he has obtained from the therapeutical use of calomel. He states that the drug has marked diuretic effects. This is very interesting as being to a great extent a clinical confirmation of Noël-Paton's results. It must here be observed that a diuretic action can only be attributed to mercuric salts, since Rutherford has shown that calomel causes no increased secretion of bile. The diuretic effects obtained by Jendrássik must be attributed therefore either to the calomel used containing a trace of the per-salt, or to its being to a slight extent decomposed in the alimentary canal with formation of the per-salt, as has been suggested in order to explain the great cholagogue effect of the drug. The action of the "blue mass" in Guy's pill must also be explained in a way similar to either of the above; either by its containing a small amount of peroxide, or by a certain quantity of the peroxide being formed in the alimentary canal.

—Alexander Krapotkin, a Russian biologist, physicist and astronomer, who was banished to Siberia in 1874, has recently shot himself in Tomsk.

---

*Jendrássik, Deutsch. Archiv. f. klin. Med., vol. xxxviii., p. 499. Collins, Medical Chronicle, July, 1886, p. 310. Stiller, Wien. Med. Wochenschr., 28, 1886. [Pract. xxvii. 219.]

†Journ. of Anat. and Physiol., Parts I. and II., vol. xx.

‡In order to prevent misapprehension of a somewhat ambiguous expression, it may be well to add that, although all the hepatic stimulants used by Noël-Paton caused an increase in the urea excreted, and in the total amount of nitrogenous excreta, two of the drugs used, salicylate and benzoate of sodium, caused a marked decrease in the uric acid excreted. The other drugs used, colchicum, perchloride of mercury, and euonymin, increased both the urea and uric acid excreted.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——A brief and well prepared paper on "Puerperal Fever," from the pen of Dr. Jacob Deutsch, of Memphis, Tenn., has appeared in reprint.

——Dr. W. C. Wile, editor of the *New England Monthly*, has reprinted his "Surgical Notes from the Case Book of a General Practitioner."

——A description of the backward dislocation of the fingers upon the metacarpus is given in a short tract by Dr. E. G. Otis, of Boston.

——Dr. John Alsdorf, of New York city, and Secretary of the New York Society for the Prevention of Contagious Diseases, in a reprint from the *Sanitarian*, discusses the prevention and dissemination of syphilis, and points out truly and forcibly the advantages which would accrue to the community from the organization of such asssociations.

—— From the New Orleans Board of Health we have a short pamphlet on the Biloxi Fever, indicating that there is little doubt but that it was genuine yellow fever.

——Dr. Nicholas Senn, of Milwaukee, in a paper before us, discusses with clearness the surgical lesions of the brain and its envelopes.

——D. C. Heath & Co., Boston, have recently published two interesting essays, one entitled "Studies in General History," by Prof. Mary D. Sheldon, the other "Modern Petrography," by Mr. G. H. Williams.

——A "Physician's Record," for preserving the clinical notes of cases, has been prepared by M. E. Hawes, East Weymouth, Mass. It is well arranged, and suitable for carrying in the pocket.

——In a reprint before us, Dr. Robert Newman, of New York city, describes the uses of the galvano-cautery in diseases of the prostate, bladder, and urethra.

BOOK NOTICES.

Massage as a Mode of Treatment. By William Murrell, M. D. Pp. 78. Price $1.00. Philadelphia: P. Blakiston, Son & Co., 1886.

The author with creditable boldness says in his preface that the range of massage as a therapeutic measure is very limited, yet it is of no little value in the cases for which it is really indicated. In this small volume Dr. Murrell tells concerning it pretty much all that is essential. He refers to its history, the method of performing it, its physiological action, and the diseases in which positive results may be expected from it. These are paralysis, joint affections, rheumatism, constipation, neurasthenia, and a few others.

Paralyses: Cerebral, Bulbar, and Spinal. A Manual of Diagnosis for Students and Practitioners. By H. Charlton Bastian, M. D., F. R. S., etc. Illustrated. Pp. 671. New York: D. Appleton & Co., 1886.

Dr. Bastian here gives the profession an exhaustive volume on the diagnosis of some of the most obscure diseases which the physician has to encounter. He divides all paralyses into:

1. Those of encephalic origin.
2. Those of spinal origin; and,
3. Those of peripheric origin.

Under each of these headings he considers first the several conditions of a pathological character which would give rise to such a lesion; next, the clinical indications which would favor the existence of such a condition; and then the regional or localizing value of special symptoms that may be associated with the paralysis. A number of diagnostic details are noted which will serve as additional guides to the clinician.

Throughout the work the author's mastery of the subject is constantly apparent, and it must take rank as without a superior in its special department.

Transactions of the Medical Society of the State of West Virginia. 19th session. Wheeling, 1886.

Transactions of the South Carolina Medical Association. 36th Annual Session. 1886. Pp. 91.

Transactions of the Louisiana State Medical Society. 8th Session. New Orleans, 1886. Pp. 306.

Ohio State Sanitary Association. Third Annual Meeting. Columbus, 1886. Pp. 86.

This list of publications indicates the constant and gratifying activity which is visible in the various medical societies throughout our country. There is no one of the volumes that does not contain articles bearing the marks of painstaking and intelligent research. We have not space to analyze each publication separately, but take pleasure in calling to them the attention of readers.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

CHYLOUS ASCITES.

We generally observe but three kinds of ascites. In one the exudation is of a serous nature, in the second it has a milky appearance, and in the third it consists of pus.

The first is the most common. The third is not so very rare, but the second is not only seldom observed, but its nature has never been satisfactorily explained. Letulle (*Rev. de Méd.*, 1886, p. 860), after a series of investigations, has come to the conclusion that the milky character of the discharge depends upon the pressure of chronic inflammation of the peritoneum. According to L., the emulsified fat found in this exudation, and which gives to it its milky color and turbid look, develops from inflammatory products, and is due to a change especially of the pus corpuscles. In evidence of the correctness of his view, he quotes the following case:

A child, æt. 3, in consequence of an uncompensated valvular disease of the heart, suffered with ascites—at least, such was the diagnosis. Paracentesis was performed several times, and after each operation fever and peritoneal pain were observed for several days. The fluid discharged after the first tapping was purely serous; after each following operation it became more and more opaque, and the fourth has a milky appearance. Analysis of the last showed:

Quantity, 1½ litre.		
Spec. gr., 1.009.		
Reaction alkaline,		
Dry residue,	2.010 grs.	in 100 fl. grms.
Fat,	0.150 "	
Albuminoid substances,	1.220 "	
Unorganic substances,	0.640 "	

L. mentions in conclusion, that the milky substance occupies the middle between the serous and the purulent fluid in its chemical position.

NEW PURGATIVES.

Though we have at our disposal a considerable number of laxatives, purgatives, and drastics, but as many of them, generally of a disagreeable taste, must be given in large quantities, and as of pure cholagogues we have but few, the recent investigations and discoveries of Dr. Desnos, in Paris (*Bull. Gén. de Thérap.*, 1886, No. 2), are of practical value.

First, phytolacin, an extract of phytolacca decandra, a chenopodiaca indigenous in our country. In doses of from 0.1 to 0.2 it produced large bilious stools, accompanied by no colicky pains of any kind.

Next, baptisin, the resinoid of a baptisia tinctoria, and juglandin, the resinoid of the juglans cinerea, also indigenous in North America, in doses from 0.1 to 0.3, also cause active and prompt purgation; but these two drugs have certain drawbacks. Baptisin often induces colic, and at least in two cases muco-purulent discharges, accompanied by blood and of a more dysenteric character, were observed after juglandin.

Finally, sanguinarin, of sanguinaris canadensis, a purgative and cholagogue, according to Rutherford, was found by D. totally without effect, even in doses of 10 grains each.

PECULIAR DIFFERENCES IN DECOMPOSITION.

The following interesting case, showing remarkable differences in the decomposition of two dead bodies of persons, who, under the same circumstances, had died at the same time, is reported by Dr. Meyer in the *Viertilj. f. Gericht. Med.*, xliv., p. 101.

Husband and wife, he æt. 72, she æt. 65, had both died the latter part of August from the inhalation of carbonous oxide. Both bodies lay in one bed; both were covered with one and the same feather-bed of not great thickness, and both dressed only in a linen shirt. The small room was quite cold. Thirty-six hours after death the body of the wife was still in good condition, while the face of the husband was already disfigured. Below the skin decomposition had already set in all over the body; at some places the epidermis was raised in blisters, and the skin itself had a brownish-red, and partly greenish color. A week later this great difference in the decomposition of the two bodies was still apparent.

The fact is of some importance in medical jurisprudence, demonstrating the possibility of decomposition, progressed to some extent, developing within the first twenty-four hours.

CAFFEIN AS A DIURETIC.

W. v. Schroeder, after a long series of observations on rabbits, was the first to make the announcement that caffein exerted an energetic, unexpectedly great influence on the secretion of the kidneys. Dr. A. Langaard (*Centrlbl. f. d. Med. Wissensch.*, 1886, July 17, No. 29,) has recently taken up the subject, and in his experiments introduced the remedy directly into the ureters while paralyzing the vaso-motor centre with chloral. L. has arrived at the same conclusion, and has besides discovered that this diuretic action of caffein is produced by the direct action of the drug on the secretory elements of the kidneys, and that it is totally independent of the blood pressure.

A peculiar incident occurs in the administration of larger doses of caffein, viz., the secretion of urine, immediately after the remedy has been introduced into the circulation, comes to a standstill, which period of inactivity is, however, very short, and the diuresis soon shows itself. For the purpose indicated, caffein is best given subcutaneously. Thein, though chemically the same as caffein, has not the same diuretic influence.

NOTES AND COMMENTS.

Calomel as a Diuretic.

Dr. F. H. Collins thus writes in the *Medical Chronicle* for July:

A. M., a strongly-built man, aged 44, of dissipated habits, came under my care on the 20th of April, 1886, suffering from cirrhosis of the liver, severe gastric disturbance, and ascites, with slight icterus. The urine was very scanty, tinged with bile, and loaded with lithates, but free from albumen. His history, condition, and aspect betokened that his illness would terminate fatally.

During the following month he took a variety of diuretics, including bitrartrate and acetate of potash, oil of juniper, and copaiba, first the resin and then the oleoresin. All these remedies, with the exception of copaiba, failed to influence the urine flow in the slightest degree, and as a rule he only passed six to eight ounces of urine daily. He commenced to take copaiba in half drachm doses on the 2d of May, and for four days the urine averaged twelve ounces daily, but afterwards the drug lost its effect. The resin had previously been tried in vain.

His condition got gradually worse till the 19th of May, when I was led to try a mercurial, owing to the diuretic influence which I have noted that blue pill has on myself. I ordered 5 grains of calomel and 5 grains of powdered ginger in a bolus, the dose to be repeated in twelve hours. The bowels acted freely two or three times, and in the twenty-four hours following the first powder 20 ounces of urine were passed, in addition to a further amount passed at stool. During the three following days the average urine discharge was 30 ounces. The dose of calomel was repeated on the 24th, and afterwards given at intervals of three or four days, and the increase in the amount of urine which

the calomel seemed to have set up was maintained for three weeks, the powder sometimes acting as a purgative, but not always. At first the man's condition was decidedly improved, and the abdominal girth decreased by about an inch, but on the 27th he had a slight discharge of bright blood from the bowel, and a little while after his general health failed still further; the bronchitis, which even at the first was a pronounced symptom, became more troublesome, and he died on the 14th of June.

Syphilitic Epilepsy and its Differential Diagnosis from Ordinary Epilepsy.

Dr. Barbier (*Th. de Paris*) thus formulates:

1. Syphilitic epilepsy manifests itself not only by epileptic phenomena, but by attacks which are such a faithful reproduction of the clinical picture of nervous epilepsy that it is absolutely impossible to differentiate the one from the other.

2. It is not due to a special virus, as was taught twenty years ago, but to cerebral and medullary lesions.

3. It is distinguished from essential epilepsy: 1st. By the absence of the cry or the aura, by the mode of succession or apparition of its crises, by the age of the patient, by the cerebral troubles, precocious or late, preceding or following the attacks (cephalalgia, vertigo, fainting, Jacksonian epilepsy)—all characters of a secondary order as regards this diagnostic value, since they are common both to epilepsy symptomatic of a syphilitic lesion and of an ordinary tumor of the brain. 2d. By the frequent co-existence of disorders of sensation in the limbs, especially the lower limbs, and by the frequent abolition of the tendon reflexes—phenomena which possess a real importance from a diagnostic point of view, since they are wanting in ordinary epilepsy, while they are quite frequent in syphilitic epilepsy; in the latter case, the brain and cord are simultaneously affected by the specific disease. 3d. By the effects of mercurial and iodide treatment.

Induction of Premature Labor: Twins.

Dr. J. R. Purdy thus writes in the *Brit. Med. Jour.*, September 25:

"Mrs. J., aged twenty-eight years, consulted me when about six months gone in her third pregnancy. Both her previous pregnancies had resulted in craniotomy. I assisted at the second, and the operation was one of considerable difficulty. So far as I could make out at that time, I thought the outlet of normal size; but the inlet, although not distorted, abnormally contracted. I advised induction of premature labor. She consented, and shortly after the seventh month, I passed a No. 12 bougie, so as to avoid injuring the membrane. Next day the bougie came out during straining at stool. There was no dilatation of the os, but there was slight discharge and pain. The pain soon ceased; and three days later I again passed a No. 12 bougie, this time with success, as pains began twenty hours after the passage of the bougie. I was called to her four hours after the first pain; I found the os dilated, admitting the ends of three fingers, and soft; the head presented high up, in the first position. The pains became very severe, without bringing the head down at all; I therefore decided to apply forceps. Considerable difficulty was experienced in so doing; when they were locked, however, very little traction sufficed to deliver the child.

"On making an abdominal examiuation, preparatory to extracting the placenta, I found the body very large, and felt what I took to be another child. I examined, and found another head presenting at the brim, with bag of waters intact. I turned, without much difficulty, and then brought the placentæ away together. The mother and children did well. Was I right in performing craniotomy?"

Narceine in Whooping-Cough.

The *Medical Record* says:

At a recent meeting of the Société de Biologie, MM. Brown-Séquard, Laborde, and d'Arsonval united in praising the effects of narceine in whooping-cough and chronic bronchitis with hypersecretion. Narceine, $C_3H_{29}NO_9$, is one of the alkaloids of opium, but exists in it to a very small amount, at most not over 0.02 per cent. Most investigators agree that in its action upon man it resembles morphine, but is milder and causes no excitement. Claude Bernard first called attention to it by his assertion that it was a safer and more agreeable drug than morphine, but had about the same sedative and anodyne effects. Narceine was carefully tried by several Philadelphia physicians, some fifteen years ago, and they concluded that it was almost inert, even in doses of from one to five grains. Froumüller states that he has given twenty grains with no effect. On the other hand, many Continental physicians (Rabuteau, Behier, Debout,

Eulenburg, Liné, and Laborde) have found that in doses of one-half to one grain it causes quietude and sleep.

The testimony heretofore has been so conflicting that doubts have arisen as to whether the same alkaloid has been used. M. Laborde now says that a very easy test of its purity is to add to the solution a drop of muriatic acid, when a beautiful blue color is produced.

Surprisingly quick results in whooping-cough have been observed by the French physicians above mentioned. The best mode of administration is to make a solution in syrup, so that a teaspoonful represents one centigramme of the drug. This is the minimum dose for children, the average dose being from two and a half to five centigrammes.

Effects of Drugs on the Sweats of Phthisis.

The *Lancet*, July 3, says that Dr. Abletsoff, who has made a number of accurate observations on the effects of various drugs upon the sweats of phthisical patients, finds that hydrochlorate of pilocarpine, given in doses of a twentieth of a grain, produces no limitation of the sweats in a very large proportion of cases; but its use frequently causes or increases gastro-intestinal irritation and sleeplessness, and, in fact, makes the general condition of the patient worse. With doses of from one-eighth to one-sixth of a grain the diurnal and nocturnal loss of weight almost always increases, and with doses of from one-twentieth to one-tenth of a grain the loss is augumented in the majority of cases. The reasons why this drug has been recommended for phthisical patients are probably to be sought in its expectorant action; but though, as a matter of fact, the amount of sputum daily expectorated is increased by the drug, it has no advantage whatever over other remedies whose effects in other directions are not so deleterious. Homatropine, picrotoxin, and duboisin distinctly decrease the cutaneous perspiration in healthy subjects, the latter drug having the greatest effect. For phthisical patients, however, who are weakened by exhausting sweats, more suitable drugs will be found in agaricin and homatropine, as duboisin and picrotoxin frequently produce other and undesirable effects.

Addison's Disease.

In the *Correspondenzblatt für Schweizer Aerzte*, Nos. 15 and 16, 1886, Dr. Ernest Kummer, assistant to Professor Kocher, of Berne, ably details two cases of Addison's disease, in one of which intense urobilinuria was present. Professor Nencki was able to isolate (by evaporating an amyl-alcoholic solution) about 0.4 gramme of urobiline from the patient's urine, collecting during twenty-four hours. Indican was nearly absent. The author dwelt on the question of the origin of the pigment which caused a "bronze" discoloration of the integuments in Addison's disease. As is known, Professor Nencki and Dr. Berdez have succeeded in isolating the coloring matter of human melanotic sarcoma, the so-called phymatorhusin, which has no relation whatever to hæmoglobin, since it contains more than 11 per cent. of sulphur (*Archiv. für Experim. Pathol. u. Pharmac.*, vol. xx., p. 346), but is closely related to hair-pigment, as Dr. Nadjeda Sieber's researches have shown (*ib.*, p. 362). It would be possible to admit that the pigment of Addison's disease is either phymatorhusin or hair-pigment; but then the urine should contain an increased amount of non-oxidized sulphur. Since nothing of the kind is observed in the disease in question (Lichtheim), the author comes to the conclusion that the "bronze" pigment is a product of hæmoglobin. He supports his view by pointing to an universal diminution of red blood-corpuscles and an absolute reduction of hæmoglobin in Addison's disease.

Reflex Pain.

Before the St. Louis Medico-Chirurgical Society (*St. Louis Courier of Medicine*), Dr. Todd said that frequently patients come with pain, and very considerable pain too, in the ear, generally confined to one ear, and upon examination there is no trouble found in the ear. Of course, in such a case the proper thing to do is to examine the mouth; and in all cases of pain about the ear, the mouth should be examined just as much as the ear itself.

A very intelligent gentleman, occupying a very important position as a city officer, came to him for treatment for pain in the ear. He examined him, and could find nothing the matter with the ear. He examined the mouth, and found one of the molar teeth on the same side with the painful ear which had been filled, and on striking it the tooth was sensitive. The doctor told him that in his opinion he did not have earache at all, but toothache. and that the pain in the ear was reflex; and to make sure that he wouldn't go away thinking that he did not know his business, he went down with him to a dentist

and had him examine the tooth. He removed the filling, and immediately gas escaped, and the patient was relieved of the pain in the ear. This is an illustration of the fact that the physician should have a good idea of dental troubles. The profession neglects them altogether too much, and trusts too much to the dentists.

Local Treatment of Membranous Dysmenorrhœa.

A paper was recently read at the Medical Congress held at Nancy, by M. Paul Landowski, concerning the application of the electro-cautery to the endometrium in cases of membranous dysmenorrhœa. The author stated that it was essential that this operation should not be performed before previously dilating the uterine orifices, and if they were sufficiently large and easily dilatable, a single application only of a prepared sponge was necessary; if, on the contrary, there should be rigidity of the orifices, the sponge must be applied twice, moving the sponge that the electro-cautery should be introduced. It was heated rapidly as it passed lightly over the surface of the endometrium. After applying the electro-cautery, the patient should remain in bed for a week. The application should be made five or six days following the menstrual period. In the case of two patients, of whom Dr. M. Ladowski spoke, one proved a complete success (in the other, the patient passed pieces of membrane the size of a penny during her periods, but she was relieved of pain. It would be interesting to know if the exfoliated processes were only limited to that part where the application had been insufficient.

Cure of Mental Diseases by Hypnotism.

M. Voisin, of Paris, read a communication at the Congress at Nancy, on the possibility of curing mental diseases by the aid of hypnotic sleep. He quoted two cases which lately came under his notice. With the first patient, sleep had not been obtained by adopting the ordinary means of looking fixedly at the experimenter. The patient's eyes were then kept open by means of two palpebral separators, and the rays of the magnetic lamp being directed towards them for ten minutes, produced sleep. In two days, the patient, who at first manifested great excitability, was completely cured. The second patient, a lypemaniac, who had refused food for a fortnight, and had made several attempts to commit suicide, was put to sleep for ten minutes, the first time by hypnotism. On awakening, she acquiesced in suggestions made during sleep, and consented to take milk. The same treatment was repeated every other day, and at the end of a month she was quite cured, and able to return to work.

Paraldehyde as an Antidote to Strychnine.

The property of paraldehyde of greatly reducing the activity of the spinal cord as a reflex centre led Professor Bokai (*Pharm. Post*) to test paraldehyde as an antidote to strychnine poisoning. The results of his experiments made on rabbits, cats, and dogs, were almost invariably favorable. The animals first received a non-fatal dose of paraldehyde, and then an absolutely lethal dose of strychnine was given. In no case did the strychnine produce death. If, however, doses of paraldehyde which are themselves fatal were given to animals, the largest doses of strychnine were not able to remove the poisonous symptoms of the paraldehyde or to delay the fatal processes. It would appear, therefore, that the antagonism between these two drugs is only one sided. On the ground that the hypnotic action of paraldehyde is much more rapidly produced than the poisonous symptoms of strychnine, the *Therapeutic Gazette* suggests that paraldehyde, if given soon after the ingestion of a poisonous dose of strychnine, might serve to antagonize it.

Ringworm of the Scalp.

Alder Smith recommends, as a parasiticide in ringworm of the scalp, chrysarobin dissolved in chloroform—7 grains to the ounce. The chloroform, in addition to serving as a vehicle, dissolves the fatty matters out of the follicles, and thereby facilitates the penetration of the chrysarobin.

A. J. Harrison applies first a mixture of ½ drachm iodide of potassium to 1 ounce of liq. potassæ. When this has penetrated, he applies a solution composed of 1 ounce of sweet spts. of nitre and three grains of bichloride of mercury. His theory is that the liquor potassæ softens the hair-bulbs and hairs, and thereby allows the iodide of potassium to be conveyed to the bottom of the follicles. Then, when the mixture of nitre and bichloride of mercury is applied (the nitre being used merely because it forms a thin mobile menstruum) the mercury comes in contact with the iodide of potassium in the bottom of the follicle and the important chemical change which is there set up—the

formation of the biniodide of mercury—he regards as very important and beneficial.

Piliganine.

Piliganine is an alkaloid which is present in lycopodium saururus, commonly known as piligan or piliganine. Dr. Bardet, chief of the therapeutical laboratory of the Cochin Hospital, tested the effect of an infusion of piligan, and observed that it acted as a powerful emetic, and produced general symptoms which indicated that it was not a suitable therapeutic agent. A chemical examination proved that this plant contained a special kind of resin and an alkaloid which M. Bardet calls piliganine. This alkaloid was isolated by M. Adrian, who gave M. Bardet two grammes of hydrochlorate of piliganine. This investigator made experiments with it on a dog, rabbit, and frog, and concluded from the resulting phenomena that piliganine acted as a poison, and that its influence was principally exercised on the nerve-centres, the medulla oblongata, and pneumogastric nerves.

Turpentine as an Antidote to Phosphorus.

The Paris correspondent of the *Brit. Med. Jour.* states that M. Ed. Rondot (Bordeaux), as the result of clinical observations and experiments, maintains the efficacy of turpentine in the treatment of poisoning by phosphorus, when taken either immediately or even some hours after the poison has been swallowed. The turpentine and phosporus combine, and are eliminated without causing any other morbid phenomena than a local reaction on the alimentary and urinary organs. It is important to administer the turpentine at the outset, so as to neutralize the greatest quantity possible of the poison. Even if it be not completely neutralized, the oil of turpentine renders the symptoms milder and favors recovery. Turpentine diminishes hemorrhage and the nervous symptoms which follow poisoning by phosphorus.

Carbon Bisulphide in Neuralgia.

Guerden recommends, as far superior to menthol in neuralgia, the application, for three minutes, of the following solution:

Carbon bisulphide (rectified),	9 parts.
Oil of peppermint,	1 part.

In superficial neuralgias, whether facial, dental, or intercostal, and in superficial rheumatic pains, this application produces instantaneous relief, and not unfrequently a cure. In the deep neuralgias, as sciatica, it is necessary to project the solution upon the painful part by means of an atomizer. Dental neuralgia usually succumbs to this treatment applied to the corresponding cheek—a slight application to the gum, or the insertion into the carious tooth of a pledget of cotton moistened with the solution being occasionally advisable.

Death from Fumes of Nitric Acid.

Three seamen recently lost their lives upon the American ship *Manopouri*, from an unusual cause. Upon opening one of the hatches, dense clouds ascended, and water was poured into the hold to extinguish the supposed fire. The men who subsequently went below, found that the hold was full, not of smoke, but of far more irritating fumes; and it was ascertained that a bottle of nitric acid, which had been shipped in a case as something else in order to save the extra cost, had been broken. The length of time during which the men were exposed to the fumes is not stated by Dr. J. W. Stickler, who reports the circumstances in the *New York Medical Record*, but no great suffering appears to have been immediately produced; within a few hours, however, the men began to complain of serious illness, and in a very short time died.

Transfusion of Saline Fluids.

At a meeting of the Zurich Medical Society, Professor Gaule made an interesting communication on transfusion of a solution containing 3.5 per cent. of cane-sugar, 0.6 per cent. of chloride of sodium, and 0.005 per cent. of hydrate of soda. As his and Landerer's experiments show, the addition of sugar leads to a rapid regeneration of red blood-corpuscles. Thus, a dog with a maximal loss of blood (5.5 per cent. of the body's weight) showed a normal number of blood-corpuscles in eight days after the transfusion. According to the author, transfusion is indicated—(*a*) when the filling of blood-vessels is altered; (*b*) when the nutrition of tissues is changed; and (*c*) when the function of hæmoglobin is disturbed (poisoning). The transfusion of saline fluids may be effective only in the first case; in the two latter cases, transfusion of blood should be performed.

Cocaine in Tooth Extraction.

Professor Redard and his assistant, Dr. G. Andina, of the Geneva Dental School, have employed hydrochlorate of cocaine as a local

anæsthetic in forty cases of tooth extraction. They used a fifteen per cent. solution, injecting into the gum in average fifty or seventy-five centigrammes of the alkaloid by means of an ordinary Pravaz's syringe. In all the cases, extraction, which was performed usually in ten minutes after the injection, was absolutely painless. No unpleasant accessory effects, except some nausea and heaviness of the head in young girls and children, were observed. The author's results, therefore, coincide with those published by Mrs. Helene Vongl-Sviderskara, of St. Petersburg (see the *London Medical Record*, July, 1886, p. 304), who, however, used far larger doses.

Tuberculosis of the Tongue.

Dr. G. Feurer, of St. Gall, publishes three rare cases of tuberculosis of the tongue. In two of the patients, in men aged seventy-two and thirty-four, the disease was primary, no symptoms of tuberculosis being found in any other organs. A third man, aged fifty, suffered from advanced pulmonary phthisis. In the latter, a cuneiform excision with suturing was performed; the wound healed by the first intention. No return of the disease has followed (two years have passed already). In another, the affected anterior part of the organ was removed by the galvano-cautery. The patient remains well. In the third, the anterior half of the tongue was excised by Kocher's method. The patient died four months later, from meningitis; no necropsy was made.

Uses of Ichthyol.

In concluding his paper on the therapeutic value of ichthyol (to which we have previously referred), Dr. Schmidt statates that the drug possesses pronounced styptic qualities, and is consequently useful in all hemorrhages and wounds. The ichthyol plaster gave better results than any other medicinal plaster used in cuts and wounds. The sticking quality of the ichthyol plaster is so intense that it does not fall off the part even when being washed. He also states that in toothache ichthyol has in his hands sustained its character of a prompt relief-bringing remedy. A drop or two of a combination of ichthyol and chloroform (one to three), placed on a piece of cotton in the hollow of the tooth, or rubbed into the adjacent gum, is certain to bring almost instantaneous relief.

Renal Inflammation from Terebene.

A correspondent of the *Brit. Med. Jour.* reports that a patient who was taking from twenty to twenty-five minims of terebene four or five times during twenty-four hours, suddenly developed intense nephralgia, and the urine became scanty, high-colored, and distinctly albuminous. There had been traces of albumen before, but it was distinctly increased at this time. There was no reason to suspect renal "colic" due to other causes. The terebene was omitted, and gradually the symptoms subsided. After the lapse of three weeks, terebene was again administered, and, as the doses were increased to the same quantity as before, a repetition of the nephralgic symptoms occurred, but less marked than before, and gradually a tolerance was established.

Ethoxycaffeine.

This body is caffeine in which one atom of hydrogen is replaced by the group C_2H_5O. Alkalies precipitate its salts from their solutions. Hypodermic injections in rabbits gave indications of a narcotic action. M. Dujardin-Beaumetz has administered this agent in cases of severe headache, and with beneficial results. Its insolubility is an objection, as is also its tendency, with other allied bodies, to cause gastric symptoms. Most of these difficulties are overcome by dissolving the drug in salicylate of soda and adding some carminatives. The largest dose given was twenty-five centigrammes. Gaurana and Paullinia owe their value in megrim to their containing caffeine.

Condurango in Gastric Diseases.

Dr. Enrique Súñer writes to *El Genio Medico* that, having recently employed condurango bark in the treatment of several cases of gastric carcinoma and catarrh, he has found it very beneficial. He gives a tablespoonful of the infusion every two hours, and in all cases the pain was decidedly mitigated and the appetite and digestion improved. In most cases of mere gastric catarrh the painful nausea and vomiting ceased, and subsequently the patients recovered from the mental depression which was due to the acute gastric disturbance. In the malignant cases, of course, nothing could be hoped for but alleviation of pain, and some improvement in the ability to take and retain nourishment.

The Function of the Tonsils.

Dr. R. Hingston Fox, in an interesting article on the Functions of the Tonsils, in

the twentieth volume of the *Journal of Anatomy and Physiology*, expresses the opinion that these glands belong to the digestive and not the respiratory tract, and that their function is to reabsorb certain constituents of the saliva in the intervals of meals which would otherwise be wasted. He thinks that the view of their having an absorbing function is further supported by the strong evidence of the power of the tonsils to absorb morbid poisons directly from the saliva.

News and Miscellany.

The Pope's Model Cholera Hospital in Rome.

A correspondent of the *Globe* gives an interesting account of the "model cholera hospital" which the pope has caused to be erected in Rome for the accommodation of cholera patients in case of an epidemic. Contact with the outer world is carefully guarded against by grated windows, telephones, and by a revolving barrel with half its circumference open, by which provisions are taken into the hospital. The water-supply is drawn from a well, and is quite separate from the city supply. The drain is formed of an iron tube sixteen inches in diameter, the joints being hermetically sealed with lead. There is a disinfecting boiler in which corrosive sublimate is placed. There is a room called the "chamber of observation," which has a staircase leading up to the first floor. In this room dead bodies are placed for a given time, as it is well known that cholera patients often show signs of being quite dead when really only apparently so. The room is, by means of an electric apparatus, in communication with the director's office. The body being laid on a bed, both hands are put into a sort of copper muff; between the hands is put an instrument so sensitive that, should there be the slightest movement of the hands or any other part of the body, this instrument would instantly close the electric circuit, and the bell in the director's office would be set ringing; at the same moment another instrument registers the number corresponding to the bed upon which the body is lying. The chamber is warmed by steam so as to facilitate resuscitation. The laboratory is provided with a gasometer for the storage of oxygen, which is taken to the wards for administration in gas-bags. On the ground floor are four wards for doubtful cases; should they get worse, they are sent up in the lift to the cholera wards above, their clothes and bed-linen being immediately burned. Another room is set apart for women in childbirth, and there are two more for undressing patients, so that the infected clothes may be destroyed, the Pope furnishing new clothing for all recovered cases. The cubic space allowed for each bed is thirty-six cubic metres. The ventilation is carried on by means of funnels with gas jets below. The chapel is in communication with the sacristy of St. Peter's, so as to form an easy access for the Pope should he wish to visit the hospital; but before returning into the sacristy his Holiness and suite would have to go into a room near it for disinfection. In the event of there being more cases than the hospital can hold, provision has been made for building large sheds in the garden. This hospital was begun in October, 1884, and finished in April, 1885. When the cholera was raging with such violence in Naples, Lao XIII. determined upon making preparations should the scourge visit Rome. It has never been necessary to use it, but it is always ready in the event of an outbreak, and should prove of much use in extirpating it.

Professor Charcot "At Home."

Dr. Kraus, editor of the *Allgemeine Wiener Med. Zeitung*, writes to that journal (Sept. 14), from Paris, a letter, in the course of which he describes a visit paid to Professor Charcot:

"My esteemed patron, Charcot, whose personal friendship I enjoy, had just returned from a holiday tour in Spain when I called upon him. Any one entering the Palais Charcot, in the Boulevard St. Germain, fancies himself in an imperial residence; and, indeed, many a royal personage does not boast of such a palace as this. Charcot is admittedly not only the oracle of French physicians, but an authority upon medicine of the highest rank. We have so often touched upon the biography of this eminent scientist in our journal, and have told our readers so much of his unsurpassable researches, that I need not now devote further words *ad majorem gloriam* of this eminent physician. Who is there among the ranks of medical practitioners who does not know Charcot and his imperishable work in the domain of cerebral disease, metallotherapy, etc? I will not therefore to-day delineate him as the man of science, but as the Paris physician to whose tapestry-covered salon troops of patients make pilgrimage, and lay

an obolus on the table, which groans under the weight of gold—from three to five or ten Napoleons a consultation. How did I know all this, if it were not that the pleasing testimony of this *aurea francogallica* practice lay piled up on the consultation table? To be sure, this modest, amiable, and highly humane French physician does not make a vain show of these offerings of esteem which his practice brings him; he simply has not time to place them under lock and ward, so rapidly does one patient press in after another. The consulting-room contains a magnificent library, which would be the envy of many a medical Universität-Bibliothek: scarcely any important work of old and new medicine, home or foreign, is wanting. Charcot, the Nestor of French scientists, reads and speaks German, and my son and myself were delightedly surprised to see lying on the consultation table the *Allgemeine Wiener Med. Zeitung,* whilst on our entering he laughingly asked whether we knew that journal. Charcot gave us so much of his valuable time that we felt embarrassed, because we had seen what a crowd of patients still awaited his advice in the fairy-like salon. We were proud to secure a written souvenir from him, and a promise to send a paper to our journal. He asked after all his Vienna colleagues—Leidesdorf, Meynert, Benedikt, and proved how exceptionally conversant he is with Austrian and German medical literature."

Chevreul Still Alive.

Chevreul has survived the celebration of his centennial birthday. The next morning after the celebration he went to his business as usual, and later attended the regular weekly meeting of the Academy of Sciences. He took no actual part in the debates, but chatted with his neighbors, and appeared as cheerful and smiling as if nothing had happened. The congratulatory address which the *doyen* received from the Academy of Sciences, Berlin, has been published. Necessarily it is very eulogistic, as the following extract shows: "He who would form a complete idea of your so busily occupied life should follow the entire course of your creative activity, which has been directed to all departments of chemistry. He must follow all the innumerable detailed researches which have enabled you to determine the nature of various minerals and of a large number of salts, as well as the composition of many organic matters. He should study your chemico-physiological works, by which you have made such great advances towards the knowledge of the most important secrets of the animal organism, as well as your labors on the most varied questions of public hygiene. He ought to follow the excursions which enable you to fix the laws of the contrasts among colors, and to class them systematically and scientifically. He ought to study your lectures on the chemical principles of dyeing. He should finally imagine himself at the period when misty ideas of the most false and fantastic kind threatened to surround and obscure the mind, and when, with the record of history in your hands, you dissipated the mists by making your countrymen recognize in the delusions of the past the errors of the present time. Having thus represented in all its extent the activity that you have shown throughout your long life, we hold that your name should be inscribed in one of the first places on the list of the great men who have carried the scientific glory of France to the extremities of the earth."

Speculum from Pompeii.

Before the St. Louis Medico-Chirurgical Society (*St. Louis Courier of Medicine*), Dr. Maughs referred to a translation from a compilation of Aëtius, which he presented at the Medical Society a couple of years ago, and that at one place that author describes a speculum in such a manner as to give a very good idea of the instrument. When he went to Naples to the museum, he found one of the instruments used by the contemporares of Hippocrates, and he had a fac simile made from this old instrument. The original was found in the ruins of Pompeii, and preserved in the museum. This instrument is at least two thousand years old, and may be the instrument Archigenes himself used. In making this fac simile they not only reproduced the instrument perfectly, but they put the rust upon it, so that any gentleman would recognize that the instrument is at least two thousand years old. The patient was placed on her back in front of a window, and this instrument introduced into the vagina, being closed while being introduced, and then the screw was turned. The assistant holds the instrument while the surgeon turns the screw, which is turned rapidly and the vagina rapidly dilated. This instrument being two thousand years old and a little rusty, works a little hard, but it is evident that the vagina can be opened very readily so as to make any application desired. If there was nothing better in the world to-day, this instrument would answer a very admirable purpose.

There are a good many old surgical instruments at the Naples Museum, and if the surgeon had nothing better, he could get along very well with them; there are scalpels, instruments for the removal of stone, delicate little scalpels and hooks, and surgical instruments of all kinds.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED OCTOBER 2, 1886.

Purviance, Geo., surgeon. Granted leave of absence for twenty-five days, September 30, 1886.

Stoner, G. W., surgeon. Granted leave of absence for twenty-three days, October 1, 1886.

Carter, H. R., passed assistant surgeon. To proceed to Galveston, Texas, as inspector, September 30, 1886.

Ames, R. P. M., passed assistant surgeon. Granted leave of absence for thirty days, to take effect when relieved, September 30, 1886.

Wasdin, Eugene, assistant surgeon. Ordered to examination for promotion, September 30, 1886.

Brooks, S. D., assistant surgeon. Granted leave of absence for thirty days, to take effect when relieved, September 30, 1886.

Williams, L. L., assistant surgeon. Relieved from duty at Mobile, Alabama; ordered to Marine Hospital, Wilmington, North Carolina, September 27, 1886.

Perry, T. B., assistant surgeon. Relieved from duty at San Francisco, California; ordered to Marine Hospital, St. Louis, Missouri, October 1, 1886.

Lead-Eating Insects.

A French architectural journal recalls an observation made by Viollet-le-Duc, that lead plates for roofing and other purposes are often pierced by insects. He accused the wasps of being the authors of the little holes which he found gnawed in lead roofs, but later observers have discovered that both worms and flies often drill through heavy plates. Some twenty-five years ago it was found that the lead bullets of cartridges, which had been stored in wooden boxes, were badly gnawed, and a number of gall or saw flies were found in the act of working upon them. Why these little creatures should amuse themselves in digging out the tough metal with their jaws, it is hard to say. Both males and females were found at work; and the only suggestion which our Gallic contemporary can make is that they were, perhaps, sharpening their teeth. The first notice of perforations made by worms seems to have been made by M. Janniard, formerly official architect in charge of churches and public buildings, who observed that the lead covering of the steps on the roof of an old house in Paris was bored through in several places. Only one of the steps was attacked; and, on looking closely, he found that every hole in the lead corresponded to a worm-hole in the oak planking on which it was laid.

A Family Weakness.

We hear of a curious poisoning case from Montreal. Rumors had been current in the east end of the city to the effect that a whole family, consisting of eight persons, had been poisoned through the mistake of a druggist in giving bug poison in place of Gregory's mixture. A reporter of the *Montreal Star* proceeded to make inquiries, and found that the "Gregory" was not in it, and that the true facts of the case were that an elderly person, named Irwin, was taken sick during the night, and got up to take some Dwight's mixture, as he thought, instead of which, the bottles not being labelled, he took a dose of liniment. No evil effects followed this. The next day his wife, who felt out of sorts, took some of the same liniment and was taken violently ill, but has since recovered. The son, some days afterwards, took some of the same liniment, and was also violently affected. The liniment contained belladonna amongst other ingredients, and neither the bottle containing it, nor any of them, was labelled.

Fasting as a Trade.

Signor Succi has succeeded in living through his month's fast, and in proving that he is a person of singular moral courage in mortifying the flesh. His fast was not absolute, since he daily partook of a small quantity of some "red fluid" of secret composition, but there seems to be no doubt that he has abstained from every other form of nutriment, if nutriment it was. French newspaper writers in search of a sensation have been prophesying ruin to the butchers, bakers, and public caterers; and as Succi is to go to Paris, to fast in public, he and his bottle of red fluid will doubtless deeply impress the public; still it is not likely that the shares of the Café Anglais will decline for

this season, though Succi may make a fortune by demonstrating the uselessness of food for a month. For obvious reasons, the fast of Signor Succi ranks rather as a newspaper sensation than as a physiological experiment of any true value.

The Doctor of the Future.

The *New York Medical Times* (homœopathic) in an editorial of true scientific spirit, says: "Go on in your sectarian course, ultra devotees of Hahnemann, if you will; be loyal to the teachings of your master, if you must; but shut not your eyes to the fact that science has rendered obsolete many tenets of his system, and removed the last vestige of an excuse for maintaining an organization of physicians under an exclusive title, distinct and separate from the medical profession at large. That ultra school of medicine has fulfilled the complete measure of its usefulness as a separate organization. Loyalty to truth and progress now demands that it shall drop its narrow sectarian name, and no longer seek to keep its members in leading-strings. In the nature of things there can be but one system of medicine recognized by science. Either homœopathy must absorb the old school or be absorbed by it.

How to Extinguish Common Paraffin Lamps.

We say extinguish *common* paraffin lamps advisedly, because all the better sorts are provided with a special apparatus for covering up the flame. It is wrong, perhaps dangerous, to blow down the chimney, and it is possibly little if at all less dangerous to turn the wick down suddenly. The best plan is to blow not down the chimney, but across the flame at the base of the chimney through the perforated wick chamber, and, of course, always in the direction of the slit through which the wick rises. A very little puff will suffice, and there is no danger in the act, because the flame is not driven down into the oil chamber but simply blown off the wick horizontally. Care must be taken to blow in the direction of the slit, or a great deal of breath may be wasted in vain.

What is Hopeine?

The *Therapeutic Gazette* says that in Iowa the word "hopeine" was on many signs where saloons were formerly kept. The owner of one of these places was arrested for the illegal sale of intoxicants. Several witnesses testified that only "hopeine" was sold at that place. The judge then asked one witness whether he knew the difference between beer and whisky when he tasted it. The witness did. "Now," said the judge, "you will tell the jury whether the hopeine that you drank was beer or whisky, and you will be committed to jail for contempt until you answer the question." "It was beer," said the witness. "At last," continues the *Therapeutic Gazette*, "we know what hopeine is. It is not the alkaloid of American hops; it is not morphine, cocaine, or atropine. It is beer."

Ricinis Communis as an Insect Powder.

A German pharmaceutical paper mentions that cattor-oil plants have been found efficacious in freeing rooms from insect life, the leaves of the plant containing a substance which is fatal to flies and other insects. There is nothing new or remarkable in this fact; but our contemporary draws from it a conclusion which, so far as we are aware, is original, and deserves a trial. It suggests that the leaves should be dried and powdered and the powder used as an insect powder, or that a decoction of the leaves would be serviceable for destroying insects.

Jews and Medical Practice in Russia.

The Russian Medical Department has been collecting statistics showing the number of Jews who are practicing medicine, pharmacy, etc. It seems that in Odessa there are of such 99 doctors (including 6 women), 3 veterinary surgeons, 9 dentists, 35 midwives, 10 feldshers, 19 apothecaries, and 4 apothecaries' managers—altogether 178. It is feared that the authorities contemplate making an order limiting the proportion of Jews allowed to engage in civil practice, in the same way as those in the military medical service are limited to a tenth of the whole.

Poisoned with Nitro-Glycerine.

An extraordinary case of poisoning occurred recently in England, through the swallowing of a quantity of a liquid containing nitro-glycerine. This liquid was prepared and used by a contractor for the purpose of blowing up the old hearths of blast-furnaces. The contractor had prepared a charge of the liquid, and placed it in a bottle in a secure place, where he considered no one could find it. A boy, aged fourteen, however, had gone into the cabin, and taken a mouthful of the liquid, supposing it to be ginger beer. The poison quickly asserted itself, and the boy died in about three hours.

A New Subject for Experimentation.

A correspondent of *The Medical Age*, referring to the occurrence of abdominal pregnancy, asks whether there is anything in the nature of the female peritoneum that renders it more fit than its male analogue for furnishing nutriment to an attached ovum, and if not, why, under favorable circumstances, ova introduced into the male peritoneal cavity might not attach themselves and proceed to a viable stage of development. He also suggests that the young of one animal might be thus grafted upon a different species.

A Scientific Windfall.

The French Academy of Sciences has just been informed of a bequest made by M. Leconte, a real estate owner of Rouen, in Normandy. The old gentleman has, by will, left to the Academy all his fortune, estimated to be fully half a million francs ($100,000). Scientists will gain by it, for most likely the income will be spent in prizes to encourage scientific discoveries, and otherwise soften the hard lot of the poor savants.

Extensive Advertising.

A printing order recently given by the proprietor of a popular remedy was for no fewer than 80,000,000 32-page pamphlets and 400,000,000 4-page circulars, at a cost of very nearly $600,000. It is said that this order will only provide the material for one year's circulation.

Artificial Tape-worms.

A writer in the *Southern California Practitioner* says that the people from the country around Los Angeles go to that city for treatment for tape-worm, and return with yards of tænia in bottles. The worms, he admits, are very pretty, and perhaps worth all they cost, far they are made of celluloid.

The Rewards of Science.

Few men who embark in pure science have been so fortunate as Professor Huxley, who at the age of sixty-two retires with pensions amounting to $7,500, viz., $6,000 as the retirement allowance from his position at the Museum of Geology and Inspectorship of Fisheries, and $1,500 from the Civil List.

Items.

—The *Atlanta M. and S. Jour.* says that Atlanta has an oculist who collects $2,000 a month from his practice.

—A Topeka mother, on being asked by the doctor whether her boy's bowels had moved, replied: "Oh, yes, he had a copious evacuation of the rinctum."

—Prof. Bartholow says that when the cause of jaundice has been removed, salicylic acid will remove the bile pigment from the blood more promptly than any other drug.

—A person brought before a police justice for some criminal offense, was asked his employment, to which he replied that he worked in a spice factory. "What particular work do you do?" inquired the magistrate. Reply: "Adulterate the spices."

—M. Bouchard has managed to induce cataract in rabbits by introducing naphthaline into the digestive canal. The quantity required for the purpose was a daily dose equal to a thousandth part of the animal's weight.

—A Vassar graduate, out in the country, went into the stable of a farm house. "Dear me, how close the poor cows are crowded together," she remarked. "Yes, mum, but we have to do it." Why so?" "To get condensed milk, mum." The sweet girl graduate went off relieved and enlightened.

—"Are you familiar with the analysis of the spring?" he said to Mr. Parvenue at Strathpeffer. "Well," she made answer, "I can't say as I am, but I'm sure there was more analysis in the water to-day than usual, for mine tasted awful."

—Patient: "Besides a headache, I don't seem to ail anything. I eat like a wolf, work like a horse, am as tired as a dog when evening comes, and at night I sleep as sound as a rat." Doctor: "Humph—hadn't you better see a veterinary surgeon?"

—At some villages in Croatia, chiefly inhabited by immigrants from Herzegovina, cholera has been present for some time, but its existence has been kept secret by the inhabitants. Physicians have been assaulted both in Croatia and Istria, the populace mistaking them for poisoners.

—At a meeting of the Berne Medico-Pharmaceutical Society, Dr. Niehans related a case of facial anthrax in a man, aged 50, where he most successfully tried subcutaneous injection of a 5 per cent. solution of carbolic acid, four syringefuls (Pravaz) at a time, around the pustule.

DEATH.

GILLINGHAM.—At Idaho Springs, Dr. H. Gillingham, of Fallsington, Pa., of pulmonary consumption, in his 28th year.

Pallas Syringe." The most useful instrument for Vaginal Medication and Irrigation.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

105-15556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,

36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

Lecture.

INTRODUCTORY LECTURE.

BY WILLIAM S. FORBES, M. D.,

Professor of Anatomy in the Jefferson Medical College of Philadelphia.

* * * *

To you, young gentlemen, I will state with much emphasis that the course you are about to pursue,* as laid down in this college by its authorities now and heretofore, is the one of all others most conducive in advancing you to the desired end, assisting you to lead out and cultivate your mental faculties while imparting technical knowledge.

So impressed am I with this belief that I hesitate not to affirm that a medical course might well be made an efficient factor in the general education of the youth of the land.

There is no study within reach of the faculties of man more justly entitled to his respect, more instructive to his understanding, or more beneficial to the finer qualities of his heart, than the intelligent examination of that wonderful organization whereby a machine of a thousand wheels, self-conservative and self-repairing, is kept in motion for near a hundred years. An ancient philosopher and physician, in examining the different parts of the body in the plenitude of his learning, records this elevated expression of of his feeling: "In explaining these things I compose a solemn hymn to the Author of our bodily frame, and in this I think there is more true piety than in sacrificing to Him whole hecatombs of cattle, burnt offerings and incense of the most costly perfume; for I first endeavor to know Him myself, and then to show Him to others, to explain to them how great is His wisdom and His goodness."

Such, gentlemen, were the sentiments of the illustrious Galen, the force of whose genius for more than a thousand years guided and ruled the medical mind with a greater sway than his master, Marcus Aurelius, ever ruled the Roman world; and who, though time and additional experience have dimmed the lustre of his name and made it less familiar to modern science, yet, in the history of the human intellect, stands forth as a half-inspired spirit whose genius for a long period formed the rallying point of everything learned and venerable in medicine.

The fervidness of feeling, and the excitement of imagination thus acknowledged by him have not been restricted to his day; for the perpetuity of the human character develops precisely the same emotions and sentiments in hundreds of persons who attach themselves to the cultivation of anatomy. * *

The difficulties that beset the first-year student are very great, and it is not by disguising or ignoring them that we shall prepare you for overcoming them. The remedy is as simple and as certain as the difficulties are many and great.

Stick to your lectures, your laboratory analyses, your dissections and your clinical work *with awill*, and the thing is done—half the difficulties will immediately vanish, and the other half will soon yield. You will have to draw on your resolution, your mental abilities, your force of character, but do not be afraid of overdrawing in such a cause.

The satisfaction of success is pleasing indeed to the noble mind in every undertaking in life. I know that the impulsiveness and

* Introductory to the Annual Course of Lectures.

the impatience of our youth naturally make the degree of exertion and industry requisite for our proper advancement anything but a labor of love. Many of us are too prone, like the camel of the desert, to lie down under our burdens, to rest satisfied with less than the bare accomplishment of our duty, to trifle away our moments of existence and become dull as a fat weed that rots itself at ease on a forgotten shore. If we desire success—I say we, you and I, my young countrymen—we should reflect that this is not the place of rest, not of rest or ease I repeat, but of steady, continuous, undeviating effort. Our work is never done, and it is the day-dream of ignorance to look for the hour as happy when we shall have nothing more to wish for and nothing to accomplish.

A chaste and lofty character comprehends not only the integrity that will not allow you, but the spirit that will not permit you, to remain idle and self-satisfied. Know you not that energy makes the imperial character of the mind, and largely imparts that grace with which it moves? The feather that adorns the royal bird supports his flight; deprive him of his plumage, and you fix him to the earth.

There is not one of you, not one in all this large class of students now within the sound of my voice, who may not, if he *wills* it, attain to all that a reasonable ambition would desire.

And now that I am permitted, in the providence of God, to stand here in this honored place to teach you the anatomy of man, the economy of the human body, after having been engaged in an active professional life of more than a quarter of a century, at home and abroad, in peace and in war, in prosperity and in adversity, I hope I may be pardoned if I venture to tell you, my young friends, what I would strive to do were I to begin again the life of a student of medicine. And in this I would address myself to every one of you individually, graduated and neophyte. First, I would form a resolution not to be shaken by anything but bodily illness; to be present at every lecture, each in its order, that I engaged to attend in this college and in the hospital during the session; and I would take down in writing then or immediately afterwards the principal facts stated by the different teachers.

Secondly. I would resolve to dissect every part of the human body with the utmost care, many times, until I had become an expert practical anatomist, and had acquired an accurate knowledge of all the viscera, all the great muscles of the body, that sustain it in the erect position, and that move it about; the ligaments and the fasciæ, and the situation and course of all the great blood vessels and nerves.

I would examine with the deepest attention all the parts of the body where surgical operations might require to be performed, all the parts concerned in hernia, lithotomy, and aneurism—the cervical, axillary, and inguinal regions more especially; and all my my dissections would be directed with reference to the human body.

I should do all this as a student; and I would take care that the knowledge thus acquired should form the foundation of my future success in my profession, whether as physician, accoucheur, or surgeon, or in all these capacities. I would constantly keep in mind the fact that no solid and enduring reputation has ever been reared upon any other foundation.

Thirdly. In the pathological laboratory I would endeavor to acquire a complete knowledge of all the changes of structure which are produced by disease in the human body, medical or surgical, in the brain, spinal cord, in the organs of respiration, and circulation, and digestion, in the liver, spleen, kidneys, and bladder, believing that some day a human life may hinge on my knowledge, and knowing that in order to attend the sick properly, the dead must be examined without reserve.

Fourthly. I would prosecute my studies to the fullest extent, and in regular order, in the laboratories of practical chemistry and pharmacy, of materia medica and physiology. I would then direct all my energies to examinations at the bedside of the sick, and in the wards of the hospital. And I would resolve steadfastly through life to continue the practice of recording with rigid accuracy all the most important cases of medicine, surgery, and midwifery that came under my care.

Lastly, I would strive in every proper way to keep in health my body and my mind. I would arrange my studies in a methodical manner; and I would so conduct myself as to retain and increase any little store of knowledge I may have acquired in letters and in arts, not knowing but that in the progress of life I may be called upon to associate with those amongst whom general knowledge would be required to support the dignity of an American physician.

Young gentlemen, now that you are about to enter upon the study of your profession, it may be well to pause for a moment and observe what is required of those who are about to enter upon their duties in other professions. The priests in the church, the lawyers in court, and the doctors in medicine are

members respectively of the three so-called learned professions. The accredited officials in each of these professions claim to be devoted to the three great interests of man—his spiritual welfare, the care of his person, and of his property. It were easy to point the divine source of one of these callings, and it would not be difficult to trace the ecclesiastical origin of the others; but perhaps it may prove interesting, if not instructive, on this occasion to observe in passing the solemn promise, the affirmation, the oath of office the applicants are made to take in the vestibule, as it were, of the temple of religion and the temple of justice, and then to place before you the now buried and long forgotten but exacting oath of office that was once administered in the temple of Hippocrates.

The church inducts her servants to the priesthood with a gorgeous ceremony, and with the distinguishing marks of her sovereign sway. The applicant at her altar is made, on bended knee, before assembled men, and in the face of heaven, to avow in the most solemn manner his unalterable determination ever to obey her ritual, to defend her faith, and to advance her cause. This oath, instituted by Gregory, enforced by Innocent, and extended by Pius, is now under Leo daily whispered around the earth with the morning angelus.

The disciple of Justinian is placed now, too, under oath; that Justinian, the vain titles of whose victories are crumbled into dust, while the name of the legislator is inscribed on a fair and everlasting monument, and who obtains with this praise from the historian of the Decline and Fall the more enviable sneer of being at all times the "pious" and, at least in his youth, the "orthodox Justinian;"—this young advocate, who is to look after the property of his neighbor, he is likewise made to swear allegiance to truth and honor.

Among the Athenians and other Hellenic nations, no particular class of attorneys existed, but each citizen pleaded his own cause before the body of the people. Later on, orators, such as Demosthenes and Isocrates, spoke for others; but they performed their duty without the sanction of an oath.

Among the Romans there were various classes of persons learned in the law and especially devoted to it; but in theory, every man who held the proud title of a Roman citizen had the privilege of speaking in the forum. The praetor and the judices constituted the court, and there were "advocati," procuratores, and juris-consulti, but I cannot find that they were sworn to their duties.

And in those countries where the civil law is now administered and where the Romance languages are spoken, I do not find that either the avouès or the advocates are sworn. They are not in France, I believe. Among English-speaking people the responsibilities, legal and moral, of the lawyer of to-day, who is now an officer of the court, arise from his relations to the court, to his professional brethren, and to his client. The oath directed by law, in this State, to be administered upon the admission of an attorney to the bar, presents a comprehensive summary of his duties as a practitioner. It is that he is to behave himself in the office of attorney according to the best of his learning and ability, and with all good fidelity, as well to the court as to the client; that he will use no falsehood nor delay any man's cause for lucre or malice; that he will support the Constitution of the United States and the Constitution of this Commonwealth.

Fidelity to the court, the fountain of honor, fidelity to the claims of truth and honor, these are the matters comprised in this oath of office.

We find this oath, with little variation and excepting its last clause, recorded in the statute of Westminster in the thirteenth year of the reign of King Edward I., in the year 1285.*

In our country it is an oath of office, and the practitioner, the incumbent of an office in the administration of justice, held by authority from those who represent in her tribunals the majesty of the commonwealth—a majesty, says a late author, truly more august than that of any king or emperor. It is an office, too, clothed with many privileges, some of which are conceded to no other class of practitioners. It is therefore that the Legislature have seen fit to require that there should be added to the solemnity of the responsibility which every man incurs when he enters upon the practice of his profession the more impressive sanction of an appeal to the Searcher of all hearts.

And now, what do we find concerning the bond of him to whom the care of the person of man is entrusted?

It may be observed that the oath of the lawyer is the growth, in the course of time arising from the responsibilities and complications of his office.

In the case of physician at present, the the law throws such barriers around the person of man for his protection, that an oath is not needed to extend that protection.

* For this information I am indebted to my legal friend, Mr. Charles McMichael.

But formerly an oath was thought necessary, and it was administered long before the existence of the civil law—yea, long before the day on which we are told the generous Evander welcomed the Trojan stranger to the hills of Latium.

I have translated this oath from the Greek of Hippocrates into English. It has been translanted before, once in the year 1597, and again of late by the Sydenham Society. But it may be well to revert to the original text. The oath is so perspicuous in itself, and so luminous as to the sacred duties entrusted to the physician of that Pagan age, that I will leave it to you to judge of its applicability to the present time.

The oath is quoted as genuine by Erotian, Scribonus Largus, St. Jerome, and others.

"I swear by all the gods and goddesses, by Apollo the physician, and Æsculapius and Health and All Heal, that I will keep this my oath and stipulation—to reckon him who taught me this art equally dear to me as my parents, to share my substance with him and to relieve his necessities, if required; to look upon his children as my own brothers, and to teach them this art, if they shall wish to learn it—and that by precept, lecture and every other mode of instruction, I will impart a knowledge of the art to my own sons, and those of my teachers, and to disciples bound by a stipulation and oath according to the law of medicine, but to none others. I will follow that practice, which according to my ability and learning I consider the best for the safety of my patient, and abstain from whatever is delereterious and mischievous. I will give no deadly medicine to any one, if asked, nor suggest any such counsel; nor will I conspire with a woman to destroy her unborn child. With purity and with holiness I will pass my life and practice my art.

"Into whatever houses I enter, I will go into them for the benefit of the sick, and will abstain from every voluntary act of mischief and corruption, and further from the seduction of women, whether bond or free. Whatever, in connection with my professional practice, or not in connection with it, I see or hear in the life of men which ought not to be spoken of abroad, I will not divulge, thinking that all such should be kept secret.

"While I continue to keep this oath unviolated, may it be granted to me to enjoy life and the practice of the art respected by all men in all times; but should I trespass and violate this oath, may the reverse be my lot."

Surely the man who wrote this instrument was inspired by a celestial Deity!

What is but the golden law of the Christian dispensation, that we should do unto others as we would that they should do unto us?

Could the physician of to-day have a loftier standard to guide him in his course?

Though this oath is not now formally administered to us, in the moral law it is as binding to-day as when Hippocrates wrote it on the tables of his temple, on the mount beyond the Acropolis.

A word, and I have done.

In the course of my remarks, young gentlemen, I have felt that whatever their truth, they lacked many recommendations they might have derived from their utterance by some other speaker. But I will now venture to state what I can say better than any of my colleagues, for none of them can so fitly as myself commend to your approbation this college which now stands upon another year of its existence; for I have hitherto had no voice in its excellent arrangements. I am still unconnected with its excellent clinical and hospital departments, one of the most important parts of that teaching which a medical college implies. But these very circumstances leave me free to express a comparatively unbiased opinion, and justify my stating the deliberate conviction that no institution on this continent offers to the student a better field of clinical observation, or a more rational and practical adjustment of the various lectures and demonstrations which claim his notice. And as every institution has its peculiarities, I may mention one or two by which this medical college is, and always has been, pre-eminently distinguished: It was the very first college in this country to give its students complete courses of lectures and practical demonstrations in clinical medicine and surgery, which have enabled its graduates to practice their profession with that marked success which has been accorded them everywhere, and which has further enabled some of her graduates to rank among the first men of this age in any country. More recently it has added to every one of its seven fundamental chairs practical laboratory demonstrations on a very extended scale. Added to this, a comprehensive summary of the practical usefulness of this college to this community may be observed when I state that in the past year fifteen thousand patients have been treated within and around the walls of its hospital. Among them may be found every accident and every complaint that you are likely to meet with in your practice.

I am very exactly informed that on this

day, within the last twenty-four hours, one hundred and three surgical charity patients and seventy-nine medical, thirty-four eye cases and forty-one gynecological, twenty-three throat and sixteen ear cases, have been treated under its roof, and that twenty-six physicians are daily employed in its charity service. What a record is this!

And now, lastly, this college has always systematically endeavored to fulfill its implied contract with the public, the profession, and its pupils, to send forth into the world carefully trained men, who by fair abilities and reasonable industry, have learned to be efficient practitioners.

This is and should be the first object of a medical school.

The genius that presides over this still advancing school and hospital is that of reform—reforms that are good, reforms that are wise, reforms that are practical, reforms that are, in a word, to the glory of God and the good of man's estate.

Let us hope, as we may well believe, that such reforms will be ever on the wing, and never cease until they rest upon the ark of abiding safety.

[At the close of the lecture the students, through the speaker of the class, Mr. James Robinson, presented a magnificent gold watch to Prof. Forbes, in the presence of the trustees and Faculty, "as a token of their appreciation of his labors as a demonstrator and their respet for him as a professor of anatomy."]

SOME INTERESTING POST-MORTEM SPECIMENS.*

BY MORRIS LONGSTRETH, M. D.,

Of Philadelphia.

The patient who furnished these morbid specimens was by trade a miner, aged 56 years, giving a history of family disease of the thyroid gland, both parents and other relatives having had enlarged throats. This thyroid is converted into a cyst the size of an ordinary kidney. It gave rise to no difficulty, though his chief suffering was dyspnœa, evidently from kidney disease. Some two years ago the patient came to the Hospital because of œdema of lower extremities, but last Monday he showed general œdema. Urine contained albumen in large proportions. Great hypertrophy of heart, dilated aorta, and atheromatous vessels. The man would probably have died shortly of aneurism.

The foramen ovale is enormously stretched, and upon the anterior surface of the heart is a light colored elevation. The constant bumping of the large heart against the under surface of the sternum has rubbed up a *wart.*

The normal heart weighs 12 ounces; this one is 26 ounces; and some fair estimate of the condition can be formed when I tell you that the dilatation greatly preponderates over the hypertrophy, which fact was proportionately bad for the patient. After death the left ventricle was filled with blood.

Kidneys enlarged, and I remove with difficulty the capsule, which leaves intact the cysts on the surface of the organ. Cysts on the surface are always due to *contraction of the kidney*, though in this case, owing to so much new inflammatory product thrown out, the kidney weighs 6 ounces.

Interstitial nephritis gave rise to the excessive dilatation and hypertrophy of the heart with its attending troubles; but *primarily* the kidneys were diseased, getting up this train of congestion of other organs.

The thyroid enlargement was congenital, *not* due to bronchocele.

Death from asthma.

* Abstract of Clinical Lecture at Pennsylvania Hospital.

COMMUNICATIONS.

A NOTE ON CASCARA CORDIAL.*

A SIMPLE, CONVENIENT, AND EFFECTUAL LAXATIVE VEHICLE.

BY R. S. HENRY, A. M., M. D.,

Of Charleston, West Va.

While medicinal efficacy is the first and most important quality to be considered in the preparation of a drug, the processes of pharmacy have now been so improved as to render it possible to retain this essential characteristic and at the same time secure palatability.

It needs no argument to convince the practicing physician of the importance of obtaining in prescriptions this hitherto much neglected condition of agreeableness. His memory will recall cases innumerable, in both children and adults, in which all the suasion or force it was possible to bring to bear was inadequate to overcome the patient's aversion to taking a medicine, or in which the rebel-

* Read before the Medical and Surgical Society of the Kanawha Valley, September 1, 1886.

lious stomach failed to serve the will, however strong, and instantly rejected the medicine that offended its susceptibilities.

That the profession to-day is being awakened to the necessity of palatable medicines, is evidenced by some recent articles that have appeared in current medical literature. Dr. E. S. Riggs, *Therapeutic Gazette*, March, 1885, p. 212; Dr. Franklin H. Martin (ibid.), January, 1886, p. 11 et seq.; and Dr. Horatio C. Wood (ibid., page 181 et seq.) emphasize the desirableness of materially improving the palatability of prescriptions; and other illustrations are not wanting to show the importance this question is assuming in the minds of physicians. While much may be done by a proper selection of the concentrated and improved forms of medicine, and by administering nauseous drugs in pills and granules or capsules, there still remain many drugs which it is necessary or expedient to administer in fluid form.

It is to render this large class of preparations acceptable to the palate that the physician often tries the whole line of vehicles, without satisfaction to himself or to his patient.

A vehicle which would combine the properties of compatibility, permanency and innocuousness, and above all possess the quality of disguising and rendering positively agreeable to the taste many of these nauseating and bitter preparations, must necessarily meet with the universal appreciation of practitioners, and be a priceless boon to their patients.

It is the purpose of this note to call attention to such a vehicle and corrigent, and to suggest a few illustrative formulæ which will indicate its very wide range of application in every-day practice.

We believe that that combination of aromatics and carminatives with cascara sagrada, known as Cascara Cordial, introduced by Messrs. Parke, Davis & Co., fulfills every required indication.

In addition to its power of disguising the taste of such bitter drugs as quinine, its gentle laxative properties render it peculiarly well adapted for addition as a corrigent to the many preparations which, given alone for any length of time, tend to interfere with the normal action of the bowels, such as the various preparations of iron and opium, than which no others are more frequently indicated and more used by physicians.

Take, for example, such a preparation as the tincture of the chloride of iron. What physician has not been compelled to desist from its use, even when most strongly indicated, on account of the marked constipation it causes? To obviate this objectionable feature of this valuable hæmatic, we may use the following formula, or such modification of it as may be desirable:

℞. Tinct. ferri chlor., ℥vj to ℥xij.
Cascara Cordial, ℥ij.
Water, q. s. ad. ℥iv.
M. Sig.—Teaspoonful T. I. D.

A very useful formula in the treatment of the anæmia and glandular enlargement of pale, flabby, scrofulous children, is the syrup of the iodide of iron combined with Cascara Cordial, as follows:

℞. Syrup ferri iod.,
Cascara Cordial, āā ℥ij.
Dose.—20 drops in water T. I. D., increased as required.

During the past year I have treated a large number of cases of phlyctenular keratitis—that form of corneal trouble so commonly met with in strumous children, and which by being simply neglected has caused the impairment of vision of so many people. In this disease of the eye, local means bear but a subordinate part to the general treatment. Tonics and alteratives are first in importance, and among them syrup of the iodide of iron, in my experience, has given the most satisfaction. Since I have been administering it in Cascara Cordial I find its efficacy much increased. I can prescribe it in larger doses and continue its use longer without experiencing any of the unpleasant effects of the iodide, and besides, I present a mixture which is very acceptable to the taste of the little patients.

In nervous debility and anæmia, and in phthisis, a combination of hypophosphite of iron with Cascara Cordial often acts very happily, especially where there is a tendency, as there often is, to atony of the muscular coat of the bowels and consequent constipation. In this condition we could use to advantage:

℞. Ferri hypophosphit., ℥ij.
Acid hydrochloric, dil., q. s. ad. solv.
Cascara Cordial, ℥iiss.
Water, q. s. ad., ℥iv.
M. S.—Teaspoonful four times a day; after meals and on retiring.

Perhaps no drug is more universally prescribed than quinine. When it is desired to produce an immediate absorption of this drug, it is preferable to give it in the form of powder or solution. Its inherent bitterness, however, renders this mode of administration objectionable to most patients. Innumerable vehicles have been tried to disguise its bit-

terness, with varying success, but we believe none has proven so acceptable as Cascara Cordial, which has been extensively used for this specific purpose, and with most gratifying results. To abort an ague fit the following may be prescribed with advantage:

℞. Quiniæ sulphat., grs. x.
Cascara Cordial, ℥ij.
Water, ℥j.
M. S.—Take at a draught.

As a prophylactic against malaria, or in all malarial remittent affections, we may combine quinine with Cascara Cordial as follows:

℞. Quiniæ sulphat., ℥ij.
Cascara Cordial, ℥ij.
Water, q. s. ad, ℥iv.
M. S.—Teaspoonful three or four times a day. Increasing the quinine when indicated.

Intermittent headache or supra-orbital neuralgia is often relieved by combining quinine with cascara. Here we fulfill two plain indications. We get the specific anti-periodic and anti-neuralgic effect of quinine, and the tonic laxative effect on the bowels of cascara. The following formula is a useful one:

℞. Quiniæ sulph., ℥i ⅓.
Cascara Cordial, ℥ij.
M. S.—Teaspoonful as indicated.

In sick headache, the above formula may be combined with caffeine and salicylate of soda thus:

℞. Quiniæ sulphat.,
Caffeine,
Sodii salicylat., āā ℥1⅓
Cascara Cordial, ℥ij.
Water, q. s. ad. ℥iv.
M. Sig.—Dose, a teaspoonful on a little finely cracked ice.

When it is desired to give the preparations of opium and to antagonize their constipating effect, the addition of Cascara Cordial to the dose of the narcotic will admirably meet the indications. Thus, when it is required to use opium for its abortive effect in the initiatory stages of incipient catarrh of the respiratory tract in the first stages of a cold in the head or cough, we may give:

℞. Dover's powder, gr. x.
Cascara Cordial, ℥ij.
Water, ℥j
M. Sig.—At a draught.

The cascara here secures a satisfactory evacuation from the bowel, and thus has a derivative effect on the catarrhal condition, which is further aided by the well-known antiphlogistic action of the Dover's powder.

It is often difficult, when necessary to give opium in some form for a long time, to counteract its repressant action on the secretions, especially on those of the intestines. It is here that the specific action of Cascara Cordial is admirably shown. It not only secures a free, painless stool, but acts also as a stomachic, improving the processes of assimilation, which are so often at fault in cases of chronic invalidism.

It would be superfluous to suggest appropriate formulæ here; to any preparation of opium used we may add Cascara Cordial in quantities sufficient to meet the indications in the individual case. In melancholia, a condition now widely obtaining among women both in the higher and lower cirlces of society, and dependent on over- or under-work and insufficient or improper nourishment, opium will often furnish the needed stimulant, though it is most important in these cases not to establish the opium habit. Lauder Brunton, in his "Pharmacology, Therapeutics, and Materia Medica," p. 724, suggests in this condition the use of the tincture of opium in doses of from five to ten minims. We could combine this with great advantage in these cases with Cascara Cordial as follows:

℞. Tincture of opium, ℥iss to iiss.
Cascara Cordial, ℥ij.
M. Sig.—Teaspoonful as indicated.

Here the patient may be kept in ignorance of the fact that she is taking a narcotic—a material aid in preventing the future formation of the opium habit. In specific disease, in scrofula, glandular enlargement, and in fine whenever it may be desirable to give iodide of potassium for a considerable time for its alterative action, no better vehicle for the drug can be used than Cascara Cordial. A useful formula is the following:

℞. Potassii iodid., ℥iij.
Cascara Cordial, ℥ij.
Water, q. s. ad., ℥iv.
M. Sig.—Teaspoonful largely diluted t. i. d. The iodide of potassium to be increased as required.

A great objection to some very valuable remedies consists in the disagreeable cerebral symptoms accompanying their administration in large doses, or in cases in which it is necessary to prolong their use for a considerable period. Thus, salicylate of sodium, which is so invaluable in rheumatism, must often be stopped at a critical period in the process of the disease, or the dose reduced, on account of the head symptoms developed; Cascara Cordial will often prevent the development of these toxic symptoms of the drug. The following furnishes a convenient formula for combining the salicylate with Cascara Cordial:

℞. Sodii salicylat., ℥j.
Cascara Cordial, ℥ij.
Water, q. s. ad., ℥iv.
M. Sig.—Teaspoonful in wine glass of water

four times daily, increasing or diminishing the salicylate as required.

The few illustrations, given but imperfectly, convey the very wide range of application of Cascara Cordial as a vehicle. The requirements of the physician will extend its use to almost all prescriptions needing correction, either on account of their bitterness or tendency to constipate. So many diseases are dependent upon or attended by disturbance of the functions of digestion and assimilation, and especially by interference with the secretory functions of the bowels, and so many valuable drugs, the use of which is indispensable, but serve to increase or perpetuate this tendency, that the application of a vehicle which secures palatableness and at the same time establishes a regular action of the bowels, must come into very general use in the every-day routine practice of the physician.

"MIDWIFERY IN THE COUNTRY."

BY WM. F. MITCHELL, M. D.,

of Addison, Pa.

An interesting article on the above subject appeared in a recent number of the REPORTER, from the pen of the venerable Dr. Corson.

Of course very few practitioners can boast of more than a minimum of his vast experience, yet, in the practice of an art so necessary, the most obscure amongst us may say something not entirely uninteresting to the youngest members of the profession. I have had something over six hundred cases of labor since I have been in practice. I have only had three breech presentations, one of the face, one of the feet, none of the shoulder or arm, and only one case of prolapsed cord. All the rest were the different degrees of head presentations, so-called. I have only had three cases of twins. The youngest mother was a primipara, not fifteen years old, confined with an illegitimate child, the oldest a multipara, forty-nine years old. I hardly know whether I am proud or ashamed to say I have never used the forceps in my life, but I am glad to know I have never had a case of lacerated perineum or a torn cervix. In looking back at this time I can see three instances in which the life of the child *might* have been saved by the use of the forceps; but when the mothers made good recoveries, who shall say which was best to do? Of course I have had a good many still-born children—I mean a good many comparatively, but none that seemed avoidable. I have the proud satisfaction of knowing that only one woman died whom I attended during her confinement, and in her case the labor was premature, and the surroundings were such that her death was a natural consequence. I have had three cases of puerperal fever, all of which recovered. I have been called a good many times after the child was born. I have had three cases of hour-glass contraction. I prefer Prof. C. H. Meigs' method of removing the placenta. He says the placenta should be "unbuttoned" much as you would unbutton your coat. There is no necessity, except in the rarest cases, of introducing the hand into the uterus. My experience teaches me that an *adherent placenta* is a *rara avis*, since I have had only three cases in more than six hundred. The placenta should be removed as soon as possible after the child is born, for it is reasonable that the sooner the parts have an opportunity to resume their normal condition the better. As I said, I have never used the forceps, but I can remember some cases in which considerable suffering *might* have been avoided by their skillful use. Still, since mothers and children did well, with the exceptions mentioned, I am very well satisfied.

Labor is, as Dr. Corson says, a natural process, and there is entirely too much interference with nature many times, with the forceps and otherwise. The temptation is very great many a time, when you are in a hurry, to use the forceps unnecessarily; but, unfortunately perhaps for me, when the necessity *did* arise in my cases, I would be be some miles in the country, and would have none with me. I am glad, however, to know that no poor woman is to-day dragging herself miserably through life mangled and torn by any forceps in my hands. Possibly it has only been my "luck," to never meet with a very difficult case, only sometimes rather protracted. Just here I will say, in regard to the support of the perineum, nothing is equal to the bare hand. Some over-fastidious person may cry out about the indelicacy of such a proceeding; but at the time when the perineum needs support, the poor woman, in her agony, is not thinking of delicacy, neither should her medical attendant—only he should do his duty as a gentleman, and I hope no man will ever enter a lying-in room who is not a gentleman.

It seems to me the advice mentioned by Dr. Corson, as given by Dr. Elliott, in regard to shaving the genitals, etc., is more

nonsensical than useless. I have never seen a case, nor can I imagine one, where such an operation would be, in any sense, called for.

After delivery, I have no doubt, syringing with a weak solution of carbolic acid, would not be bad practice. Nothing is better, when the os is rigid, than a moderate dose of morphia, using the fingers at the same time as a dilator. The tying of the cord is as necessary as anything else in the practice of obstetrics. The natural instincts of animals, notably cows, leads them to ligate the cord by torsion—licking it with the tongue—and since hemorrhage sometimes follows even after the cord has been tied, it seems to me there can be no argument in regard to this matter. Anyhow, a person can feel comparatively safe after the cord has been carefully tied. The old plan of dressing the cord with grease of some kind is useless; a dry, soft rag, with a hole in it, doubled a few times, is better.

I do not agree with Dr. Corson in regard to the use of the binder. How would he, or any other man, feel if he had recently had a tumor weighing eight or ten pounds, with a gallon or two of fluid, extracted from his abdominal cavity? Methinks there would be a feeling of "all-goneness" that would loudly call for a support of some kind. The skin and integuments have been on the stretch for months, the last few weeks to the utmost tension—in some women so much so that the corrugated appearance of the skin remains ever afterwards; the intestines lie limp and loose; the folds of the abdominal walls fairly overlap each other; the emptiness, so to speak, of the cavity, so recently bulging out with its contents, is painful; the back is tired and sore. Why, then, should there not be a binder for support to all the parts? The binder should be good, and stout, and broad. It should not be too tight, nor worn too long. Before applying the binder the condition of the uterus should be ascertained, if it seems to be firmly contracted, so that it appears as a firm, hard body when grasped with the hands; then the binder can be applied with the certainty, almost, that the patient is all right.

I have never had any trouble, so far, with post-partum hemorrhage. Venesection is the sheet-anchor in convulsions, both before and after delivery.

The suffering of women during labor is sometimes terrible to see, but if a delivery is carefully conducted, I have yet to see a woman to whom strength sufficient was not given to bear up under the ordeal.

SOME DISORDERS OF ADOLESCENCE, ESPECIALLY IN GIRLS.

BY JOHN M. KEATING, M. D.,

Of Philadelphia.

There is a large amount of literature on this subject, but it is mostly confined to monographs or articles appearing in popular magazines. These do undoubtedly a great deal of good, but at the same time it seems to me that there is a medical side of the question which is equally important.

We all recognize the very great importance of impressing upon mothers the value of all that tends toward muscular development in growing girls. They should be symmetrically developed, should have full chests, straight backs, and strong limbs. We should also urge the importance of clothing of light weight and loose fitting, the principal strain being on the shoulders, not on the waist and hips, and also the evil results of cramped, stooped positions in the school-room, eye strain, and bad ventilation. We all urge these matters daily, and we all know but little attention is paid to them. But there are certain forms of various disorders which occur about the time of the second dentition which deserve more than a passing notice. These are manifested either as a chorea, nervous excitement such as night terrors, and various mental disturbances misnamed hysteria, gastro-intestinal disorders, and evidences of mal-nutrition. The child will probably become languid, suffer with frontal headache, become peculiar in her disposition and show fits of temper, shun society of other children, lose her appetite, become despondent, and possibly develop a local twitching of some of the facial muscles. It is customary to say that this is all reflex,* is possibly the warning that the system is undergoing some change preparatory to the menstrual functions—that it is in fact a true hysteria. This may or may not be the case. My own impression is that it is often due to the anæmia brought about by rapid growth and development, with faulty assimilation and deficient oxygenation. In my experience such cases present two types, the one essentially nervous, just described, the other the so-called strumous or lymphatic, in whom the want of proper assimilation is shown by a large amount of stored fat, and the anæmia by excessive pallor.

Sufficient attention has not been called to the disturbances caused by the pressure of the twelfth year molars. These may show themselves in either dental neuralgia, or, in fact, any form of trifacial neuralgia, gastric disorders, or mental peculiarities, amounting to melancholia or symptoms of acute meningial irritation.

In the first case, the mother will tell you at once that her child cannot take iron, that she has frequent nose bleeds, and that she feels confident that if iron could be given it would be of great service. The nervous system seems to run riot, but this very excitement in itself is an evidence of the demand on the part of nature for a blood supply which is nutritious and well oxygenated. All the exercise in the world, all the most nutritious and sustaining of foods, will have no effect, until the digestive organs are made to perform their normal functions. If you examine the tongue you will find it coated, the breath is heavy, the bowels are sluggish, the appetite is perverted, the child craves extraordinary articles of food, especially acids and sweets. She has a disgust for her regular meals. There is flatulence, cardiac palpitations, asthma after exertion. The urine is either scanty and high colored, or very copious and of low specific gravity. If the menses have been established they are scanty, colorless, and irregular, or there is a leucorrhœa. In these cases the recommendation of popular writers for gymnastics, friction, mild diet, etc., are admirable after the digestive organs have been cleared of their accumulation of ashes, and the normal functions whipped into activity. For an infant I have the greatest confidence in small doses of calomel, with soda bicarb. and ipecac, frequently repeated; but for the cases we now speak of, I much prefer the following:

℞. Acid nitro-muriat. dil., ♏ xl.
Succus. Tarax., ♏ lxxx.
Vin. pepsini, q. s. ad. ℥j.
Sig.—Teaspoonful in water after meals three times daily, with a half teaspoonful of the fluid extract cascara sagrada every night until the bowels become regular.

After taking these for a few days, if the tongue has become clean, the complexion clearer, the patient can be placed on the following, instead:

℞. Hydrarg. chl. corros., gr. ⅛.
Liq. arsenici chlor., ♏ xij.
Tinct. ferri chlor., ℥j.
Syr. limonis, ℥j.
Aquæ, q. s ad. f℥ vj.
Sig.—Tablespoonful after meals, and the laxative continued, if necessary, at night.

As far as the general treatment is concerned, the little patient should be sponged every morning with tepid water, she should stand in a tub, and have a pitcher of it poured down her spine from the nape of her neck, and then be thoroughly rubbed with a soft Turkish towel into a glow. The breakfast should consist of milk warm, or cocoa, a soft-boiled egg, or rare pieces of steak or chop, either oatmeal, cracked wheat, grits, or Indian meal alternating; bread and butter, with hot cakes. For dinner soup, rare meat, fresh vegetables, very little water. For supper, stewed fruits, bread and butter, warm milk or cocoa, with tea, not coffee. She should retire early, and not be permitted to read at night. The supply of oxygen should come from out-door exercise, not an over-indulgence in walks or games that fatigue; let the school hours be limited to the early part of the day, and avoid that abomination of preparing lessons in the afternoon or evening for next day's recitations.

In about a week's time the girl will be able to bear the iron alone, and the tincture of the chloride can be given in ten or fifteen drop doses for some time, or a chalybeate water can be given with arsenic. The digestive organs will now also tolerate milk in large quantities, provided it is of medium richness, is fresh, and given warm.

But this is not all. There are very many cases of a highly nervous type, which, despite the most careful treatment, will not improve at home. The constant association with parents of like temperament, however solicitous they may be in carrying out instructions, is of itself a cause of nervous irritation.

It may be necessary to send such children from home, either to some relative, living possibly in the country or some distant city, or perhaps to some suburban or country boarding school, where a thorough change of air and scene, the association with girls of a different temperament, will work wonders.

For the strumous type, the same preparatory treatment may be instituted, and for such I would not hesitate to push the iron, phosphates, cod-liver oil as soon as possible. Change of air to the sea-shore is advisable. There is little trouble in the home treatment on these latter cases; there is rarely a conflict if authority in such families.

Although I have intimated that the ovaries have little to do with the production of these conditions, I feel satisfied that the weakness, constipation, faulty clothing, eye strain, or dental pressure, will eventually tend to the production of uterine derangements—anæmia being the cause, due to deficient assimilation, from digestive disturbances, want of fresh air and healthful exercise, reflex irritation, and afterwards uterine disorders follow—*post hoc* instead of *propter hoc*.

Medical Societies.

PHILADELPHIA CLINICAL SOCIETY.

Dr. Amy S. Barton in the chair.

The paper for the evening—

Operation for Abdominal Fistula, and Removal of Gall-Stones,

was read by Dr. Marie B. Weiner.

Mrs. S. came to me, in May, 1883, to see what could be done for a fistula, located about one inch below, and three-fourths of an inch to the right of the umbilicus. This had existed about 2½ years, remaining open and discharging a muco-purulent fluid. The history is as follows: During October, 1880, the patient, for a period of two weeks, had an attack of fever, and although there were morning remissions and evening exacerbations, it never left her entirely. This was accompanied by severe pain, particularly on the right side, which was best described as being similar to colic. There was also a general tenderness, and her skin was compared, by her sister, to the color of old gold. After this attack passed off she enjoyed good health until some time in the following January. Early in this month she lifted her mother, unaided, into bed; and a few days later, whilst walking along the street, slipped in such a manner as to throw her body backward, but did not fall. This accident was followed by a sudden pain in the abdomen. A "lump" formed, six or seven inches diagonally upwards from the umbilicus, on the right side, about the size of a large fist. This would partially disappear, at times, but never entirely. The whole side had a greenish, yellowish discoloration, similar to that of a bruise, which gradually assumed a dark-red color around the umbilicus.

Some time in March, 1881, a small vesicle appeared a little below and to the right of the umbilicus, which the patient pricked with a needle. A thin liquid, mingled with some pus, escaped therefrom.

She poulticed it only at intervals, being somewhat undecided what was the proper course to pursue. Finally allowing her physician to see it, he informed her that it was a fistula, and that it would have to be laid open; but this was never done, and the patient continued to try the various remedies prescribed, without the desired result. It would still continue to gather and break, and she soon learned that most comfort was derived if the track were kept open, to allow free drainage. At a later period, the date of which could not be recalled, a small concretion, as large as a grape-seed, escaped from the opening, but it was not preserved. There was no bile in the discharge.

When I first examined the patient a bluish spot was seen, about the size of a ten-cent silver coin, one inch below and three-fourths of an inch to the right of the umbilicus, somewhat raised above the surrounding tissue, an opening in the centre.

The probe entered four inches, with very little resistance and no pain, passing upward to the right and almost directly inward. It was thought an abscess had formed in the abdominal wall, for though questioned carefully she denied any jaundice until *after* the operation, and then too for the first time was any mention made of the small body like a grape-seed.

Packing with oakum was first resorted to, without the desired result; then injections of nearly all the irritating liquids at command in such cases were used; but the fistula continued open.

An operation was strongly opposed by the patient, and since no other benefit had been derived from treatment except comfort, it seemed as though the only course was to continue the injections.

I succeeded in obtaining a consultation with Prof. W. W. Keen, who during the examination, succeeded in introducing the probe six inches, it seeming to take a more direct course posteriorly. Prof. Keen advised an exploratory incision, which was made May 1, 1884. At 2 o'clock p. m., on that date, the patient being etherized, a probe was introduced, and its direction determined by counter pressure. An incision was made diagonally over the probe, in the direction of the liver, about four inches in length, dividing, successively, the integument, subcutaneous fat, and muscular tissue. The fistulous track was thus laid open, and I was enabled to insert the probe two inches farther, when it struck a resisting body, suggesting a bone, or more likely a calculus. I then dilated the canal with a pair of hæmostatic forceps, and as this was done a small calculus fell between the blades, and lodging there was withdrawn with the instrument. The character of the fistula was now determined. A small rent in the fascia beneath the transversalis muscle, made by the process of stretching, was brought together by three catgut sutures; the remaining stones were then removed, numbering, in all, eleven. They were whitish in color, round in shape, not faceted; the largest was about the size of a hickory-nut, and the smallest about as large

as the head of an ordinary black toilet pin. Careful search for more proved fruitless, though both probe and finger were used. An attempt was made to determine whether the cavity, at the internal end of the fistula, was the gall-bladder or a false cavity, but no positive conclusion was reached. The cystic duct could not be found.

The wound was washed out carefully with a stream of carbolized water (5 per cent.), a large drainage tube inserted the length of the track, the parts brought together by seven wire sutures, and dressed with antiseptic dressings. The patient was permitted to sit up for half an hour on May 14th, just two weeks after the operation, and from that time gained strength steadily. During her confinement to bed, her temperature fluctuated between 98.4° and 101°, reaching the higher point but few times during her illness.

For the first few days there were some nausea and vomiting, which were controlled by the administration of brandy and aromatic spirits of ammonia.

The wound was dressed the day after the operation, the bandages being soiled with blood. On the fourth day after the operation, the discharge became purulent, and so continued.

On June 11 the patient visited Dr. Keen, at his office; the drainage tube had in the mean time been changed to one of smaller calibre, but of the same length as the one first introduced. The discharge was still free, and of a muco-purulent character, Dr. Keen suggested daily injections of a solution of gtt. xl. tinct. ferri chlor. to f℥j. of water, and to shorten the drainage tube. This was done with the view of determining if a communication existed between the tract and the duodenum. The injections were continued for ten days, but with no dark discoloration of the fæces. The discharges were, however, materially lessened, and I again shortened the drainage tube, leaving only about 1¾ inches. I then began using injections of unguent. nit., grs. xv. to f℥j., every other day, with continued improvement.

During the period of twenty-four months there had been two profuse discharges of pus from the tract—the exact amount discharged unknown; these were preceded by great pain, radiating along the right side, and between the shoulder blades. After the last discharge of pus I was able to insert the probe 6¼ inches, passing slightly upwards and almost directly inwards, producing sharp pain, which caused the patient to gasp. My patient is in no better condition since being operated upon than she was previously.

She will cheerfully submit to a second operation, *provided* a reasonable prospect of recovery can be assured to her.

Mary Willets, M. D.,

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, September 2, 1886.

The President, B. F. Baer, M. D., in the chair.

Intubation of the Larynx.

Dr. E. E. Montgomery exhibited a set of Dr. O'Dwyer's tubes, the gag, and the instruments for the insertion and removal of the tubes. He related the history of a case of laryngeal diphtheria, in which they were successfully used to relieve asphyxia. In consequence of an overdose of stimulant the tube was coughed out, and had to be replaced, as the child could not breathe without it. The doctor contrasted the difficulties of tracheotomy with the comparative ease of introduction of the tubes, and called attention to the want of success attending the former operation, as parents will not give an early consent for its performance. He had performed eleven tracheotomies before he had a single successful case, and as his first intubation case has been a success, he feels strongly in favor of the new operation.

Removal of the Ovaries for Uterine Fibroid.

Dr. M. Price: The case is one of interstitial uterine fibroid; the uterus being about the size of one at the third month of pregnancy, irregular in outline and nodular, and pelvic-bound. The ovaries were displaced backward and incarcerated between the uterus and sacrum, making it difficult to remove them. The woman had been suffering four years, and a confirmed invalid during the last one, unable to do any work. Her marital relations had been suspended for over a year, owing to the sickening pain attending any attempt at sexual intercourse. She had to walk with great care and lie on her stomach while resting or sleeping, to prevent a throbbing and sickening pain in the pelvis. A rather exceptional and interesting feature of the case was the absence of profuse and irregular bleeding. Her menses were irregular, scant and pale. Her chief suffering was from engorgement of and pressure upon the ovaries. All kinds of treatment had been persevered in for the last three years, and the patient grew worse. She demanded operative procedure for her relief, preferring the risk of death to her suffering. The ovaries were removed July 9,

1886. They were hypertrophied. They were found low down behind the uterus. They contained numerous pus pockets. The tubes were enlarged, but did not contain pus. With the exception of a suture abscess, she did perfectly well, and made a perfect recovery. She is now able to look after her domestic affairs, and is free from pelvic pain and soreness.

No examination of the condition of the uterus has been made since the operation.

CHICAGO MEDICAL SOCIETY.

OFFICIAL REPORT.

Stated meeting, October, 20, 1886.

E. J. Doering, M. D., President, in the chair.

Dr. Charles Warrington Earle entertained the Society with a very interesting account of his recent trip abroad, referring more particularly to observations made in the

Hospitals of Paris and the Laboratory of M. Pasteur.

He first visited the Hospital Lariboisière, which has an outside and inside obstetrical department in which 3500 women were confined last year. This hospital has 875 beds, and the several pavilions are disinfected by carbolic acid, and thoroughly washing everything in them with solution of bichloride of mercury. But the favorite antiseptic is the biniodide of mercury. An interesting feature in this hospital is the contrivance for keeping up the body heat of prematurely born infants. It is a square box so constructed as to prevent the loss of heat, the top of which is covered with glass. In the upper part is placed a thermometer and a little basket with soft clothes, in which lies the baby. In the lower part of the box is an arrangement for the introduction of hot air, either from the heating apparatus of the building, or by heating air by gas or hot water bottles. For infants younger than seven months the temperature is maintained at 100° to 105° F. Between seven and eight months the temperature ranges from 85° to 100° F. The children are fed with breast milk when possible, and are not handled or exposed except when absolutely necessary. By using this incubator they save a large number of the lives of the prematurely-born infants. The Maison d'Accouchements is Tarnier's private hospital. Although not a modern hospital, asepsis is aimed at, each patient being isolated and having her own irrigator, the permanganate of potash being the favorite antiseptic. Carbolic acid is sprayed in the wards continually. In turn he visited the Hospitals Bichat, Tenon, and Hôtel Dieu, in all of which the rule is cleanliness and disinfection. Dr. Earle said his most interesting visit was to the dispensary and laboratory of M. Pasteur. The dispensary was smaller than the number of patients demands, and here Pasteur spends his forenoons, exercising a supervision over the treatment of the scores of unfortunates who go daily to be inoculated for hydrophobia. Nearly every country on the globe has sent patients here. Dr. Earle then explained the mode of preparing the virus. He said, also, that the majority of scientists on the continent are satisfied that M. Pasteur is honest in his endeavors to prove that he has discovered a cure for hydrophobia, and that they are simply waiting for time to prove if such be the case. They have great confidence in Pasteur, and believe that at the proper time he will announce the truth.

EDITORIAL DEPARTMENT.

PERISCOPE.

Infantile Cerebral Paralysis.

Dr. R. Norris Wolfenden thus writes in the *Practitioner* for September:

The disease to which we may thus give the name of cerebral infantile paralysis may be described in the following terms: A healthy child is attacked with one or more convulsions, vomiting, and fever, which may last for a day to two or three weeks, or may be so slight as to be scarcely recognized. Complete hemiplegia results, and if it is of the right side of the body, speech is generally affected. Sometimes the paralysis is manifested as a monoplegia of arm or leg, and more rarely it assumes a paraplegic form. At this stage the little patient may remain for a longer or shorter time unconscious; in one of my cases coma was said to last for forty-eight hours. In other cases

the initial attack is transitory, and the child appears well in a few hours, but a partial or complete hemiplegia has resulted.

This completes the first stage. Facial paralysis is rare, but strabismus not unfrequently is met with. The second stage is that of recovery, and may be said to last until a stage when permanent mental defect is first noticed, accompanied frequently with epilepsy. The recovery during the second stage is tolerably complete, the leg usually being the first to amend. There is always, however, loss of power on that side, and inability to adjust the actions of the limbs for fine movements. Athetosis is generally marked. The recovery from the paralysis is usually followed by some degree ot shortening in the limb, and though the muscles are not atrophied there is usually a difference in the circumference of the limbs. the arm and leg of the affected side measuring less than their fellows of the opposite side. The sensation in the limb, which may have been affected during the initial stage, is usually perfect. The tendon-reflexes are exaggerated. The limbs retain their usual warmth.

At a variable period it is noticed that the child is late in talking, or fails to talk intelligibly. True epileptiform attacks often develop, and the child grows up *non compos mentis*, or truly epileptic. This constitutes the third stage.

The muscles never exhibit any electrical degeneration reactions, and contraction to the faradic current is perfectly maintained.

With regard to the *etiology* of this disease, it seems so far to be doubtful how much heredity is concerned. Strümpell noted two cases (out of twenty-four) which he ascribed to blows on the head. I think dentition had to do with at least two of my cases. Ranke does not attribute his eleven cases to any particular etiological cause. I have seen one case follow measles. Strümpell has also seen one case after measles and one after scarlet fever.*

With regard to the *age* of the patient, out of Strümpell's twenty-four cases seven were under one year old, eight from one to two years, four from two to three, and five over three years old. One was only four weeks old, and the eldest was six years. Ranke's eleven cases occurred all before the fourth year. My cases occurred, three under one year, one between one and two years old, and one at four years old. Thus out of forty cases, nineteen occurred under three years of age, thirty-four under four years, and only six over four years of age. The disease is. therefore one of early infancy, and thus resembles the spinal form of the disense.

The *initial stage* may last from two to three days to as many weeks, and is ushered in always suddenly, sometimes with extreme severity, sometimes almost without any convulsions at all, the first thing noticed being hemiplegia.

In one of my cases *unconsciousness* was said to have lasted for forty-eight hours. Probably, as Strümpell suggests, many fatal cases of so-called convulsions are due to the severe initial stage of this disease.

Athetosis occurred in seven out of Ranke's eleven cases. I noted it in three of my five cases. These athetotic movements occur probably in the majority of cases, but as Strümpell's remarks are sometimes rendered evident only on movement of the limb.

In four of my five cases the *intellect* was affected. Ranke noted this in three of his eleven cases.

The supervention of *epilepsy* is common.

The *prognosis* as to partial recovery of the affected side is good. Probably there is always some impairment of power and permanent dragging of the foot, and inward turning of the ankle. Where speech is lost at first the prognosis as to recovery must be very guarded. Sometimes it remains unintelligible. Epilepsy must be expected to supervene as the child grows older. Though some cases appear to recover permanently, it is probably the minority, and the prognosis will therefore be very guarded, or even distinctly unfavorable. It must be borne in mind that many of these cases are attended with complete loss of intellect.

With regard to *treatment*, it is probably not often that one is fortunate enough to see the patient at the earliest stage, and there is little to distinguish the case from one of convulsions due to other causes. In a later stage, cod-liver oil and tonic treatment will be indicated. I have found much benefit from the use of the constant current. Where the intellect is hopelessly impaired, moral treatment will be necessary. When not mischievous, most children in this condition have strong imitative faculties, and these can be turned into a useful channel.

*Gaudard (Contrib. à l'étude de l'hemiplégie cérébrale infantile: Thesis, Geneva, 1884,) considers congenital syphilis to be a cause.

A Case of Acute Inversion of the Uterus.

The patient, 22 years of age, was at term with her first child. One morning, without the slightest warning, the membanes gave way. Twenty hours later the os uteri began

to dilate, the head presenting with the occiput forwards and to the left. The perineum was very rigid; and delivery was effected, by means of the forceps, of a child weighing nine pounds, without any laceration of the perineum. After attending to the child, compression was exercised on the uterus, but no traction was made on the cord. The woman was directed to bear down, and while so doing Dr. Wecks noticed that the globular form of the uterus gradually became less marked. The placenta came down, but its removal was followed by a fairly copious hæmorrhage. On introducing two fingers to ascertain the cause of the flooding, a large tumor was found occupying the vagina, which turned out to be the uterus in a state of inversion. He then passed the whole hand into the vagina and pressed upon the uterus, reduction being effected in two or three minutes. A dose of ergot was given and the uterus was held in place, ice being applied to the abdomen until contractions set in. On a further examination, a pyriform body could be felt projecting into the vagina, consisting of part of the uterus. By means of compression, etc., the inversion was completely reduced in about half an hour. Recovery took place without any unfavorable symptoms. The case is interesting as tending to show that uterine inversion may take place without (1) abnormally short umbilical cord, (2) traction on the cord, (3) irregular compression of the fundus or too energetic bearing-down efforts, and without (4) undue rapidity of labor. Dr. Wecks is of opinion that the proportion of such cases usually given (1 in 190,000) is in reality far too small. He points out that it appears to occur indifferently in delicate and robust subjects, after slow as well as in rapid labors, and in the practice of skilled attendants as often as when none such is available; finally, that traction of the cord and compression of the fundus are, after all, only exciting causes.

Gastrotomy for the Removal of Foreign Bodies.

In the *Archiv. für Klin. Chir.*, Dr. Credé, of Dresden, reports a case in which he successfully extracted from the stomach of a man, aged 24, a large denture consisting of eight false teeth. This foreign body was removed fifteen days after it had been swallowed, and the patient made a good recovery. Appended to this paper are three tables of cases that have been collected from different sources by the author's assistant, Dr. Koch. The first of these tables contains references to ten cases of gastrotomy for removal of foreign bodies, in which the stomach at the time of the operation was not adherent to the anterior wall of the abdomen. In eight of these cases the operation resulted in recovery; a remarkable success, it is pointed out, as four of the cases were treated before the introduction of the antiseptic method into surgical practice. Such result, Credé holds, should induce surgeons to have less hesitation in removing from the stomach, in suitable cases, a foreign body the size and form of which render its spontaneous discharge impossible. In the second table are arranged nine cases, in which the stomach was adherent to the abdominal wall. Of these one only was fatal. The third table contains seven cases, the details of which were not given fully and clearly in the original published reports. Of these, so far as can be made out, one was fatal. Of twenty-six cases in all, in twenty-two the operation proved successful, and in four only was it attended with a fatal result.

The Use of Benzoic and Salicylic Acids in the Treatment of the Typhoid State.

At the meeting on the 25th of June of the Hospital Medical Society of Paris, M. Robin criticised the general antipyretic treatment, and proposed a new method. He asserts that the danger to the patient's life is due to the organism being encumbered with the broken-down incompletely oxidized organic products. These bodies are with difficulty eliminated, because of their slight solubility. To his theory of elimination, M. Robin has given the name of "solution by combination." The principal medicinal agents used are salicylic and benzoic acids, which combine with the nitrogen radicles of the effete tissues and are carried off by the urine. M. Robin first tried the physiological action of benzoic acid and the benzoates of soda on combustion, and gave them to healthy individuals for some days, who were fed on generous diet. The constant effect was a diminution of the solids excreted in the urine. This action M. Robin attributes to the benzoic acid lessening combustion. Afterwards he gave the benzoic acid in five typical cases, and found the amount of urine and contained solids to be increased in each case. The same result was obtained by salicylic acid and its salts. M. Robin makes further experiments with methyl, salicylic acid, etc., which he considers act in a similar manner to salicylic acid. M. Robin thinks in this treatment we have the best way of treating typhoid fever and typhoid states, which he considers are caused by the retention in the

system of incompletely oxydized waste products.

Four Cases of Spurious Hermaphroditism in One Family.

Before the Obstetrical Society of London, Dr. Jno. Phillips gave this family history: Out of nine pregnancies, the fourth, sixth, eighth, and ninth were hermaphrodites. Fright during the third month of pregnancy, in the mother's opinion, caused the first. None of them survived more than a few days, and the author had an opportunity of post-mortem examination. The family antecedents were very carefully gone into, many of them being personally examined. Several defects, such as hernia and the like, had been discovered. A genealogical tree was appended. The author gave a historical view of the whole subject. There appeared two causes at work on the mother's side, in the production of this deformity:

1. The initial fright which she received when pregnant with the first.

2. The continued dread and mental distress which ensued on her bearing a deformed child.

The following conclusions were drawn:

1. A hernial or other weakness present in one parent, acting as a predisposing cause, any deep maternal impression received about the third month, might induce some impediment to the proper differentiation of the urogenital system.

2. A distinct tendency towards bearing hermaphrodites might be developed in a mother who had already borne one.

Case of Dysidrosis of the Face.

Dr. Jackson states (*Journal of Cutaneous and Venereal Diseases*, No. 1, 1886), that on August 13, 1885, Mrs. K. presented herself at the New York Polyclinic for treatment of a chronic eruption on the face. It occupied the lower half of the forehead, surrounding both orbits, occurring below both eyes, and on the sides and bridge of the nose, and running down on each side of the nose for a short distance on the upper lip. It had the appearance of large and small sago-grains scattered over the affected parts, and consisted entirely of fully distended vesicles with clear contents. The largest vesicle was about the size of a split French pea, the smaller ones were the size of a pin-head. They were generally discrete, though here and there closely crowded together. A few had apparently joined at their edges, and some of them were of a darker shade than the others. Central puncta were visible in a very few. When pricked, a clear fluid with acid reaction escaped from them. They did not rupture of themselves, and their covers offered considerable resistance to the lancet. The skin otherwise was perfectly normal, and free from any appearance of inflammation. When slightly rubbed with a handkerchief, the skin became easily hyperæmic. There were a few dilated blood-vessels upon the nose.

Two Cases of Reunion of Cut-off Fingers.

In the *Russkaia Meditzina*, Dr. S. D. Ivanoff, of Briansk, furnishes details of two interesting cases occurring in healthy soldiers, one of whom had accidentally cut away, by a stroke of an axe, the second phalanx of his right forefinger, while another had severed in the same way the second phalanx of his left thumb. In the former, the part hewn off was still united to the hand by means of a bridge of skin about two centimetres in breadth, the axe having passed through the first interphalangeal articulation, and chipped off a part of the base of the second phalanx. In the other case, the chopped off part was brought away in a glove; the weapon cut transversely a little above the interphalangeal articulation. In both of the cases the cut was clean, without any crushing of the parts. The first man was seen two hours after the accident; the second, three hours. The wounds were washed with a corrosive sublimate or carbolic solution, and the severed parts were accurately fixed by sutures in their normal situation, after which an iodoform dressing was applied. In both perfect union by the first intention ensued, with return of sensibility and (limited) mobility.

Hereditary Bullous Eruption.

Joseph (*Monatshefte für Prakt. Dermat.*), observed in a woman, aged 37, who was well nourished and strongly built, bullæ and vesicles on the soles, the sides, and backs of the feet; also upon those parts of the trunk which were subjected to pressure by the corset. They were not accompanied with inflammation, and were not painful. They shrank and became dried in a few days. The patient was the subject of no other affection, although urticaria factitia was easily provoked. The interest of the case consists in the fact that two children, boys, of this woman suffered from the same affection. In them it was limited to the feet. In all three, the affection was worse in winter than in summer.

Is Medicine a Progressive Science?

The *Med. Press* says that under this title Dr. Morell Mackenzie has contributed an article to the *Fortnightly Review*, in which he favors the lay public with his views on the progress or otherwise of medicine as an art. The object of his article is apparently to show that the practice of medicine is frequently merely a matter of whim or theory, and that *bona-fide* improvements are in the main attributable, not so much to ingenuity or research on the part of the followers of Æsculapius, as to the inventive faculty of students of the allied sciences. As instances of this, the microscope, laryngoscope, etc., are mentioned. Surely, however, some credit is due to the profession for having utilized the increased facilities placed at its disposal —facilities which, so far as the laryngoscope and similar instruments are concerned, are not by any means of recent date, since the principle upon which they are constructed is as old as the hills. Doctors have as much right to claim credit for applying the microscope to diagnostic and physiological purposes, as has the painter who employs colors in the production of a picture. It is scarcely to be expected that doctors actually engaged in practice shall find time for close and tedious investigations in the collateral sciences, any more than a soldier in the thick of the combat can formulate a plan of attack, The workers have, however, in no small number of instances, been medical men whose means and tastes have allowed them to leave the beaten track and so contribute to the advancement of science by original researches.

Dr. Mackenzie is good enough to admit that some progress has been effected in matters therapeutical. He considers that "less physic is given, but it is prescribed with a clearer purpose." We must be thankful for small mercies, but even here we are inclined to ask to whom we should be grateful for the change? Is it not to physiologists, for the most part medical men, that we owe whatever we do know as to the precise action of the drugs we use? and do clinical observation and experience go for nothing in determining how, when, and under what circumstances particular agents are to be employed? On the whole it seems scarcely just to divide the laurels of the profession between the instrument makers and the chemists. They are useful, nay indispensable handmaids, but nothing more.

The varying nature of the conditions under which the medical man is called upon to intervene, renders his advances precarious, and this is doubtless accentuated by the innate tendency of most men to be satisfied with what they know, to the exclusion of further research.

If habits and customs maintain in the conduct of members of the professsion *vis-à-vis* the public which might, so far as any benefit to patients is concerned, be advantageously relegated to the limbo where so many other antiquated customs lie mouldering, their persistence is largely in deference to popular prejudice. The sentiment which obliges the medical man to don the tall hat and semi-clerical attire, expects and requires to be treated by pills and potions, purges and plasters, on the lines laid down by past generations of practitioners. The advance of knowledge, however, enables the modern Æsculapius to attenuate what might otherwise be undesirable results by the substitution of anodyne remedies for the more heroic measures of our forefathers.

Successful Gastrostomy.

William Square, F. R. C. S., reports this case in the *Brit. Med. Jour.:*

J. W., aged sixty-two, a monthly nurse, was admitted on April 10, 1885. For some months, she had had progressive difficulty in swallowing. About a week before admission, she came to an absolute stop. Her history was good. Some blood in the vomit, and increasing tenderness, prevented the passage of any tube. Without operative interference, it was evident that she must die very soon.

On May 1, 1885, the first part of the operation of gastrostomy was performed after the usual custom. The stomach was easily found, and silver sutures were used. Nutrient enemata consisting of beef-tea and brandy, with some tincture of opium, were given every four hours.

On May 3, the stomach was opened with a Gräfe's cataract-knife. A soft India-rubber tube was introduced, being retained in place by a suture passed through it; one ounce of peptonized milk was given every two hours by the tube; in addition, one enema was given every five hours.

On May 9, peptonized strong beef-tea (two ounces) was given every three hours by the tube. The temperature was always normal, and there were no symptoms after operation but slight retching for two days. She was discharged on May 23, 1885.

On April 6, 1886, she looked almost as well as ever. She had traveled to Brighton and back, and, by the courtesy of the guard, fed herself *en route* in a separate compart-

ment. She always lay down to feed. There had been an interval of one month, during which she could swallow as well as ever, even hard meat and crusts. During all this month, however, she vomited mucus and blood until the capability of swallowing ceased.

She was in the habit of making her day's food each morning—a large basinful of beef-tea, bread, and milk. She injected as much as she wanted when hungry. Her meal-times corresponded with those of the family. Her mouth watered before. The only thing that she could taste injected was whisky. It had the usual alcoholic effects. She appeared very well, and it seemed that the diagnosis of carcinoma might be wrong.

On April 14, 1886, she was taken suddenly ill with vomiting, and a condition of semi-collapse. A large amount of green, highly-offensive pus was discharged by the side of the tube. She slightly recovered, but, up to the time of her death, took in but little, and was constantly sick. The green pus was always exuding, more or less, by the side of the tube. She became gradually worse, and sank on April 25, 1886.

Remarks by Mr. Square.—At the necropsy, the whole of the lower part of the œsophagus was one enormous ulcer; but there was no thickening nor suspicion of cancer. The whole mucous membrane was simply destroyed. It was very offensive. The mucous membrane of the stomach was not healthy, but had nothing very remarkable about it. The orifice of the hole was very peculiar. I had expected to see it valvular, or dilated into a funnel; but it was no larger inside than out, being perfectly circular, and about the size of a No. 16 catheter. There was a little left pleurisy, but nothing else to record. I think we may say that the poor woman had one year of happy life, without ache or pain; and hence I am justified in calling this a case of "successful gastrostomy."

Case of Severe Gun-shot Injury of the Wrist-joint and Fingers; Treated after the Conservative Method.

Dr. Evgeny M. Vostrikoff, of Stavropol, details (*Proceedings of the Stavropol Medical Society*) the case of a peasant, aged 28, who was admitted with a wound of the left hand, which had been caused seven days before by his gun bursting at its breech part while he was shooting at a wolf. On examination, the thumb and the ring and little fingers were found to be torn from the adjoining metacarpal bones, and in a sloughy condition. Their metacarpo-carpal joints were laid bare, their soft parts crushed and hurt, and altogether transformed into "something like gruel." The wounds were dirty and offensive; the integuments of the wrist and lower part of the forearm were tense, red, and hot; and the whole extremity up to the middle third of the arm was swollen. The man suffered from fever (102.4° F.), rigors, giddiness, pain in the injured limb, and general weakness. The author resolved to preserve for the patient the use of his hand (that is, the use of his intact middle finger and forefinger), and accordingly removed only the dead fingers and thumb by cutting through the wrist-joint. The anterior articular surface of the trapezium, as well as the surgical wound in general, remained bare, since there was no sound skin left to cover the parts. The wound was washed out with a 0.2 per cent. solution of corrosive sublimate, and dressed with gauze soaked in an 0.1 per cent. solution of the drug. About a week later an abscess was detected on the lower third of the forearm; it was opened and drained. About three months later the patient was shown to the Stavropol Medical Society with all his wounds healed; the movements in the wrist-joint and preserved fingers were yet limited, but at all events retained to give a more or less useful limb. Dr. Vostrikoff mentions three other cases of severe injuries, where he has successfully followed conservative principles instead of performing amputation. In one of the patients there was a perforating bullet-wound of the shoulder-joint. He recovered with but trifling limitation of movements. Another had a compound comminuted fracture of the leg; about fifteen splinters were removed through the wound; complete union took place in three months, the limb being shortened only about half an inch. In a third case, the toes and metatarsus were crushed by a wheel of a railway carriage; the injured parts fell away spontaneously, leaving a good stump in two and a half months. Dr. Vostrikoff's case induced Dr. P. S. Korniavsky to relate a case of his own (*l. c.* No. 9, 1885, pp. 8–10). A boy, aged 8, received a clean cut into his right thumb with a large kitchen-knife, the wound occupying the dorsal half of the thumb, and so penetrating into the interphalangeal articulation as to leave it completely open. Under a dressing consisting of English adhesive plaster and iodoform gauze, the parts united by the first intention, the thumb preserving all its movements to their normal extent.

Ingluvin.

It has been a favorite saying among the more distinguished of our profession, that there are a few essential drugs without which the practice of medicine would be impossible, and that when we have selected these few, the great multitude of articles in our materia medica are comparatively useless. This is a very true idea. With calomel, opium, castor oil, quinine, mercury, and a few such standard drugs, the physician is usually equipped to meet all emergencies. Almost weekly some new drug is brought to our notice, but in many instances, after trial, it is found either inferior to, or no better than, those which we already have, and its use is dispensed with. But it does sometimes happen that we are offered an article of such undoubted merit that it is warranted in taking rank with the *standard* articles of our materia medica. Such an article is ingluvin. (Ingluvin is a refined substance prepared from the ventriculus callosus gallinaceus, the gizzard of the domestic fowl, gans domesticus.) It is the essential principle of the gizzard, and bears the same relation to poultry that pepsin does to the higher animals.

A favorite prescription of Chinese physicians for chronic indigestion is to cut up and digest chicken gizzards in hot water until they are reduced to a pulp, and then add some spices. A tablespoonful or two of the resulting paste is taken at each meal until the patient has entirely recovered. From China the practice passed to other parts of Asia, and was adopted here and there among the Mediterranean peoples. Strange to say, it was never learned by the great nations of Europe until the latter part of the present century.

The diseases in which the use of ingluvin is indicated are indigestion in its various forms, known as dyspepsia, and for sick stomach or nausea caused by debility of that organ. It was originally discovered to be a remedy, indeed a specific, for vomiting in pregnancy; in this respect it stands above all other medicinal agents. In all that is here set forth the manufacturers claim no more than is sustained by medical authority of the highest standard.

In ingluvin, the physician has what might be called a specific for a sickness which in many cases has hitherto been uncontrollable.

Ingluvin is a powder of a yellowish-gray color, and may be prescribed in the same manner, dose, and combinations as pepsin, three to ten grains. The pulverulent form is considered more desirable, and it can be administered either dry or in water, milk, or tea. In sickness in gestation, the dose may be increased to ten or twenty grains.

The following will make a nice formula in which to prescribe it for the vomiting of pregnancy. It was thus used successfully by Dr. George F. Meeser, of this city:

℞. Ingluvin, ℥i:
Bismuth snit., ℥ss.
M. Div. in chart xii.
Sig.—One every 3 hours.

Oxalate of cerium may be prescribed with it, one to three grains to each dose.

Dr. Shelly recommends the following formulæ for diarrhœa, cholera infantum, and marasmus:

INFANT FORMULA.

℞. Ingluvin, gr. xij.
Sacch. lac., gr. x.
Misce et ft, cht. No. x.
Sig.—One every 4 hours.

℞. Aquæ calcis, f℥ij.
Spts. lavand. comp.,
Syr. rhei arom., āā f℥j.
Tr. opii, gtt. x.
Misce. Sig.—A teaspoonful every 2 to 4 hours.

FOR ADULTS.

℞. Ingluvin, ℥j.
Morphiæ sulph., gr. jss.
Misce et ft. cht. No. xii.
Sig.—One every 4 to 6 hours.

℞. Aquæ calcis, f℥ijss.
Spts. lavand. comp., f℥ss.
Syr. rhei arom., f℥vj.
Tr. opii, f℥ss.
Misce. Sig.—Dessertspoonful every 2 to 4 hours, or after each evacuation.

The substance ingluvin without any combination has also yielded almost constantly satisfactory results.

Dr. Roberts Bartholow, who probably stands to-day as the greatest authority on materia medica in this country, speaking of ingluvin, says:

"Ingluvin has the remarkable property of arresting certain kinds of vomiting—notably the *vomiting of pregnancy*. It is a stomachic tonic, and relieves *indigestion*, *flatulence*, and *dyspepsia*.

"The author's experience is confirmatory of the statements which have been put forth regarding the exceptional power of this agent to arrest the vomiting of pregnancy. It can be administered in inflammatory conditions of the mucous membrane, as it has no irritant effect. Under ordinary circumstances, and when the object of its administration is to promote the digestive function, it should be administered after meals. When the object is to arrest the vomiting of pregnancy, it should be given before meals."

Reviews and Book Notices.

Book Notices.

A Text Book of Operative Surgery and Surgical Anatomy. By Arthur Trehern Norton, F. R. C. S., etc. Based on the original work of Professors Claude Bernard and Ch. Huette. Second edition. Illustrated by 88 plates drawn from nature and engraved on steel, and many woodcuts. Bailliere & Co., London and Paris, 1886. (Philadelphia, for sale by D. G. Brinton.) Large 8vo. *colored* plates. Half Russia. Price $12.50 (by mail, postpaid and registered).

Probably no surgical work was ever offered to the medical public with finer engravings, both as regards technical execution and anatomical accuracy, than Bernard and Huette's *Chirurgie Operatoire.* The present volume, based upon that celebrated production, makes use of many of the same plates, and adds others not less carefully prepared, together with many woodcuts.

The text has been entirely re-written under the supervision of the eminent English surgeon, Mr. Norton, with the assistance of a number of distinguished London specialists. By their aid, it has been extended to include all surgical operations of standard value and approved by the best living authorities. Thus, besides the general operations which every surgeon and every physician must be prepared to perform, if he would meet the usual emergencies of professional life, the work gives full details, always elaborately illustrated, of the operative surgery of special branches. The chapter on Ophthalmic Surgery has been prepared by Mr. Silcock; that on Diseases of Women, by Drs. Handfield Jones and Wiltshire; that on Aural Surgery, by Mr. Field; and other equally well-known British specialists have contributed chapters on Lithotrity, Osteotomy, and Renal Operations. In this manner, this work may be considered a compendium of the whole domain of operative surgery in its most recent and authoritative expression.

The descriptions of the operations are clear and practical. The anatomy of the parts is first explained, and the relations of the adjacent vessels and tissues carefully set forth; then follow the steps of the operation, minutely detailed one by one, with the variations in it which may be advantageous under special conditions, as anomalies, etc. The steel plate illustrations which accompany each description are colored after life with scrupulous fidelity, and bring the steps of the procedure to the knowledge of the reader almost as completely as a dissection itself.

A Text-book of Naked-eye Anatomy. By James Cantle, M. A., M. B., F. R. C. S., etc. Third edition. Illustrated with 113 Plates, engraved on steel after designs by Prof. Masse. Bailliere & Co., London & Paris, 1886. (Philadelphia: for sale by D. G. Brinton.) Large 8vo. *colored* plates. Half Russia. Price, $12.50 (by mail, postpaid and registered.)

The colored steel plates of Professor Masse are unique of their kind, faithfully executed, and afford the best means of obtaining an exact knowledge of anatomy, or keeping that knowledge fresh in memory, short of actual dissections. Without some such work as this, the physician who does not or cannot frequent the dissecting room will infallibly lose the precision of his anatomical facts, and with that a good deal of his certainty in diagnosis and confidence in his operations. As anatomy is the foundation of all medical and surgical proficiency, it is the first duty as well as the most direct interest of every physician to keep clearly in his mind the macroscopical or naked-eye anatomy of the body. To accomplish this, there is no other way open to him than by frequent consultation of such a work as the one before us. It covers the whole of the economy, beginning with the bones, and proceding to the muscles, glands, nerves, vascular system, genital organs, organs of special sense, etc.

All of these are illustrated by carefully colored full-page steel plates, 113 in number, many of which contain four or five separate figures. The relations of the parts are shown by different hues and shadings, so that at a glance one perceives the various tissues and their positions. The extreme delicacy of the technical work on these line engravings renders them models of artistic execution, and their accuracy places them in the first rank of anatomical illustrations.

The descriptions in the text are succinct and lucid. Constant reference is had to the figures and to the numbers designating the separate parts. The English names are employed in preference to the Latin wherever the custom of the age permits it, and this we agree is a sign of advance. The anatomy of special organs is treated with unusual fullness, and the aim of the author is constantly to avoid useless details, and to convey in the most direct manner possible the idformation essential to the student and practitioner.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa.

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

PRACTICAL MEDICAL JOURNALISM.

By *practical* medical journalism we mean such journalism as is calculated to be of *practical* use to the *practical* physician in the every-day practice of his profession. In this great country of nearly 60,000,000 of people and more than 80,000 physicians, there is to be found, as we might expect, a large number of medical journals, varying in the way in which they are conducted, in order that they may suit the particular class of physicians for whom they are intended. Notably we have two extremes. First, we have the large weeklies, full of long-winded, deep, scientific articles, that are of comparatively little *practical* value, since it is necessary to wade through many pages of matter that possess very little interest for the busy physician, and consume his valuable time in order that what little of value is therein contained may be extracted. No one can call such a journal *practical*, however valuable it may be to the man who has the time and inclination to acquaint himself with the literature of medicine.

Secondly, we have the cheap monthlies, whose cheapness is their chief recommendation. We had better say *low price*, rather than *cheapness*, for in medical journals as in any other articles of merchandise that which is low-priced is not always cheap. As a rule (of course there are exceptions) these low-priced monthlies are worth all that is asked for them; but if a man imagines that he will get for one dollar a year all the journalistic aid that he requires in the practice of his profession, we fear that his estimate of what is required of our noble calling must be a very inferior one.

Then we come to the "happy medium class," and it is in this category that we have always endeavored to keep the REPORTER, during the *thirty-three years* of its existence. Our idea of a journal for the busy physician is that it should be so conducted as to assist him to recognize the nature of a disease or an injury when it confronts him, and tell him how to restore his patient to health, and to do this with as much conciseness and brevity as is consistent with a clear understanding of the subject. That the *practical* physician also entertains this same view of *practical* journalism, is amply evidenced by the fact that the REPORTER always has been, and is, recognized as the journal of the mass of the profession, of the busy, practical physician. We have no use for, and do not publish long-winded, wordy articles. Whenever a Society or Hospital Report from any part of the world is *practical*, we publish it. In

our Periscope and Notes and Comments we briefly and concisely record all that is worth knowing. We editorially discuss the questions of the day, and in our department of "Queries and Replies," we afford the subscriber the opportunity to procure any desired information. In a word, we think that we publish the most useful and most practical medical journal in the United States. If there are any physicians who differ with us, we would like to have their views on the subject.

TREATMENT OF CATARRHAL ICTERUS.

Catarrhal jaundice is a disease which presents so many various degrees of severity that it is difficult to determine the value of any kind of treatment without knowing the type of catarrhal inflammation of the bile ducts with which one has to do.

In our experience there are three main varieties of this disease—one, which invariably brings about a fatal issue when the ducts finally close up; then the opposite, a form so mild that often within a week all indications of jaundice have disappeared, and with them the malady itself; and, finally, a slow, sneaking type, which drags on for weeks and months, and which—if uncomplicated—always ends favorably, but which often seems to be the forerunner of graver lesions, that after a year or two cause the death of the individual.

It is especially with this last variety that we have here to do. Here the treatment is often very unsatisfactory, and there are many cases where all our procedures seem to be followed by no benefit to the patient. In Napheys' Therapeutics, Engel recommends a method which makes use mainly of the function of the kidneys to eliminate the bile, and which as a rule probably is the most successful treatment in the general run of cases. But though improvement under it always sets in, we meet with cases here and there where the disease nevertheless drags on for weeks and months.

Dr. H. Löwenthal in the *Berl. Klin. Woch.*, 1886, No. 9, recommends Krull's irrigations in just these slow cases, and from his report we judge that this method offers advantages possessed by no other. Krull's procedure is as follows: The patient daily receives an injection of cold water per anum, about one or two quarts of the fluid generally being sufficient.

Löwenthal treated 41 cases of catarrhal jaundice by this method. In all cases (with the single exception of one where the observation could not be carried to the end on account of the patient's not returning) rapid and favorable results were obtained. In children the quantity injected each time amounted to one litre (about 1 pint); in adults, from 1 to 2. The temperature of the water was as follows: First day, 12–13° R.; second day, 15–16° R.; third day, 18; Fourth and eventually following days, 18–24° R. Generally after the third injection the stools assumed a yellowish tint, and after the fourth they were invariably brown. After the second and third injection appetite returned, and the feeling of discomfort and lassitude disappeared. All other phenomena ceased as rapidly.

The treatment is so simple that it well merits a general trial. Its mode of action may be thus explained. In catarrhal icterus there is an increased quantity of blood in the upper part of the duodenum; if large quantities of cold water are injected per anum, a revolution takes place in the intestinal circulation, and this is ultimately followed by hyperæmia of the rectum, thus bringing about for the time being anæmia of just those parts that have too much blood. To it must be added the peculiar revulsive action of cold water, probably induced by the effect which it has on the splanchnic nerves.

Notes and Comments.

The Alleged Poisonous Properties of the Common Parsnip.

Two of the contributions from the department of pharmacy in the University of Wisconsin (*Pharm. Jour.*) are devoted to the subject of the alleged poisonous properties of the root of the common parsnip (*pastinaca sativa*), when growing wild. It appears to be a popular belief in some parts of the United States that if the edible roots of the cultivated parsnip remain three years in the ground they revert to the wild form, and then possess poisonous properties. Mr. J. T. Bennett failed, however, to separate from wild roots any principle that produced poisonous symptoms when administered to the lower animals, and Mr. Wells gives direct testimony that he has eaten, both cooked and raw, roots from a parsnip patch that has been allowed to run wild for probably half a century. It is concluded, therefore, that the frequently-reported cases of poisoning by wild parsnip root ought to be attributed to one or other of the umbelliferous roots re-

sembling it, which are known to possess poisonous properties.

Suppurating Venereal Bubo; with Remarks on a Method of Subcutaneous Treatment, and Report of Cases.

Twenty-one successful cases entitles the treatment which Dr. Scott Helm reports in the *Chicago Med. Jour.* for September to further trial.

"The parts are thoroughly cleansed; the ether spray is used for the purpose of local anæsthesia; then the canula, attached to the stop-cock section and mounted on the trocar, is inserted into the centre of the abscess; the trocar is withdrawn and the stop-cock turned in order to prevent the introduction of air. The barrel is then attached at its sliding-joint and the pus withdrawn and the quantity noted. The barrel is then carefully washed and a two per cent. solution of carbolic acid injected and the cavity thus washed out. After this has been withdrawn the iodol or iodoform, suspended in the oleic acid, is injected, in like quantity to the amount of pus evacuated, after which the needle is withdrawn and the point of entrance, after being carefully dried, is coated with a film of collodion, and a compress and bandage applied over all."

Remarkable Injury of the Finger.

M. Thomas, of Tours, has described to the Paris Society of Surgeons a remarkable injury of the third finger which has come under his notice. One of his patients, going home late without his key, wished to climb an iron railing with sharp-pointed tops. When dropping down, he felt himself retained by his third finger, which gave way at last; and, going into his room, he found that his finger was completely stripped of its integuments. A medical man, called at once, found the finger caught on the railing by a ring. The finger appeared complete, but was without the bone. M. Thomas was called an hour after, and reintroduced the bone into the finger. He applied two sutures, and bandaged the hand. The extremity of the finger became gangrenous. However, the patient had from this attempt the benefit of preserving nearly a phalanx and a half of his finger. M. Thomas has not found any such case on record.

Native Plants Injurious to the Skin.

The object of the paper which Dr. James C. White presented to the American Dermatological Association was to show that the number of plants growing native and cultivated in the United States, which are capable of exciting some degree of dermatitis by contact is much larger than is generally supposed, and that cases of such inflammation of the skin not infrequently occur without being understood, because the patient has not been exposed to the two or three plants which alone are considered to be poisonous. He enumerated over fifty species which have irritating properties when brought in contact with the skin. With reference to rhus poisoning, the speaker said that the rhus toxicodendron was comparatively innocuous, while the rhus venenata was the most poisonous species of this plant. The treatment is the ordinary treatment of dermatitis. There is no specific for this form of dermatitis.

Treatment of Acute Gonorrhœa.

In the *Medical Age* Dr. W. M. Casey says that about November 10, 1885, a mechanic, aged 26 years, came to him with acute gonorrhœa. He prescribed at intervals different remedies for injection common to the ordinary treatments, but they did not have much control over the discharge.

At the end of four weeks he became worried, the patient being of good family and "good pay." It occurred to him that normal liquid ergot might serve a good purpose, and he prescribed as an injection normal liquid ergot (P., D. & Co.'s), one part; water, six parts.

This was on December 12, 1885. On December 22d, he returned representing marked improvement. The discharge had almost ceased. At this time he repeated the formula. This sufficed to complete the cure, for January 5th he called to pay his bill, stating that he was well. In all he had used only f.ʒiij of the normal ergot, diluted as stated.

Aconitine as an Anæsthetic in Diseases of the Eye.

Dr. Pierd'hovy, of Milan, (*Recueil d'Ophthalmologie* 5, 1886,) has made some experiments with the salts of aconitine, including the oleate, the hydrochlorate, and the valerianate, with the view of substituting them for cocaine. The solutions used were of the strength of 1 per cent., and two or three drops were instilled into the eye. He found that in the course of two or three minutes anæsthesia as complete as that produced by cocaine was induced. It does not seem, however, that in

this form the salts of aconitine can be used as substitutes for cocaine, since after the lapse of a short period the conjunctiva becomes congested, and heat and pain are complained of, which extend to the cheek and to the lips of the same side, and there is sometimes lachrymation. The anæsthesia lasts for twenty or thirty minutes, and disappears, together with the pain, in the course of an hour or two. The pupil at first contracts, then slightly dilates, and finally resumes its normal diameter.

A Solvent for Sordes in Ataxic Fevers.

Dr. A. D. MacGregor, of Kirkcaldy, speaks highly of boric acid as a topical application in the unhealthy condition in which we frequently find the mouth, tongue, and teeth in severe cases of typhoid fever (*Brit. Med. Jour.*, July 10, 1886). He says:

"The mouth is hot; the lips dry, cracked, and glued to the sordes-covered teeth by inspissated mucus and saliva; the tongue dry, or even glazed and hard, brown or black, and crusted with a fœtid fur. Under these circumstances, a pigment containing boric acid (thirty grains), chlorate of potassium (twenty grains), lemon juice (five fluid drachms), and glycerine (three fluid drachms), yields very comforting results. When the teeth are well rubbed with this, the sordes quickly and easily become detached; little harm will follow from the acid present. The boric acid attacks the masses of bacilli and bacteria, the chlorate of potassium cools and soothes the mucous membrane, the glycerine and lemon juice moisten the parts and aid the salivary secretion."

Salol.

This new compound, introduced by Mencky, is a derivative of salicylic acid, one atom of hydrogen of which has been replaced by the phenol group (*Pharmaceutical Jour.*). Possessing antipyretic and antiseptic properties, it is hoped that it may prove of service in cases in which the salicylate of soda is badly borne. Its physical characters are those of a white powder of faintly aromatic odor, almost insoluble in water, and perfectly tasteless. In the organism the compound becomes split up into the salicyl and phenol elements; both may be detected in the urine, which becomes very dark, as happens after the ingestion of carbolic acid, of which salol contains thirty-eight per cent. The splitting of the compound is believed to take place in the duodenum, under the influence of the pancreatic digestion. It is remarkable that no toxic symptoms appear to have resulted from the employment of salol.

Treatment of Painful Chronic Cystitis.

The following suggestion for painful chronic cystitis has been found to be very efficacious: Crystallized nitrate of silver, one gramme; distilled water, fifty grammes. This is injected in cases of painful chronic cystitis. After the patient has passed urine, an explorator, with a perforated bougie, No. 12 to 14, is introduced until the urethral sphincter is reached, and from twenty to forty drops of the solution are injected. The necessary number of injections, and the time which should elapse between administering them, varies. If the patient has only suffered three or four hours after the first injection, it is repeated every other day; but, if the pain continue for one or two days, it is better only to administer an instillation once or twice a week, and to decrease the number of drops. This remedy succeeds very well in cystitis of a gonorrhœal origin, but should not be used in cases of cancer, or tuberculosis of the bladder.

Intestinal Obstruction from an Unusual Cause.

Dr. E. T. Gould, of Sonora, Cal., writes to the *Med. Record* that he was called on the morning of June 27 in consultation upon a case of obstruction of the bowels occurring in a patient fifty-eight years old. Laparotomy was advised, but as the attending physician did not concur in this, it was decided to use morphine hypodermatically in sufficient doses and with sufficient frequency to produce entire freedom from pain for forty-eight hours, and then to give a full dose of castor-oil. The treatment was ineffectual, and death occurred on June 30. Five hours later the autopsy was made. The cause of the obstruction was found to be strangulation of four feet of the ileum by a loop of diverticulum. The diverticulum, an inch and a half in length, was from the ileum, and its tip had become adherent to the bowel as a result of previous inflammation. It was located three feet from the ileo-cæcal junction.

Hyperpyrexia and Rapid Development of Pneumonia.

A highly interesting case has recently been observed at the Western Fever Hospital at Fulham (England). A woman, æt. 27, was admitted at midday, on September 13, with profuse scarlatinal desquamation over the

entire surface of the body. Her temperature on admission was 101.4°, and she complained of no pain. However, at 6 p. m. her temperature was 106°, and a few fine crepitations were detected at the right base. At 10:40 p. m. she was violently delirious, and became rapidly unconscious, dying at 11:15 p. m. A quarter of an hour before death her temperature rose to 110.4°, and loud mucous râles were heard. At the autopsy there were found some slight recent pleurisy, extensive œdema, and marked early red hepatization of both bases, but especially the right.

The Surgical Treatment of Hepatic Abscess.

It has become a surgical axiom that the earlier an abscess is evacuated the better. But in the literature the opinion seems to predominate that these abscesses are an exception, and some authors even go so far as to advise non-interference. "With our present knowledge of antiseptic surgery," says Dr. L. L. McArthur (*Chicago Med. Jour.* for September), "I believe a diagnosable abscess of the liver can be opened without increasing the patient's danger, either by Volkmann's or Grave's method. Certainly the plan of 'laisser faire,' of 'letting nature take its course,' ought to be given up, and dependence not be placed simply upon the routine treatment by tonics, stimulants, and anodynes."

Poisoning by Squills.

Squills and tolu are household remedies, and when baby has a cough he is dosed with them. But Dr. E. B. Truman reports several cases of fatal poisoning by squills in the *Lancet* (September 4), and he concludes:

1. That squills is not a safe drug to use for routine, and especially popular or lay practice.

2. That being so variable, and when strong so potent a drug, it should be looked upon by the profession as unsuitable for use until a solution of standard strength can be produced.

3. That in the meanwhile its use should be discontinued.

Phosphorus in Intermittent Fever.

A Russian provincial practitioner, Dr. Sochinski, states that during a rural practice of five years he has found phosphorus a valuable remedy in intermittent fever. He prescribes the oleum phosphoratum in the form of emulsion, a drachm in six ounces, of which a tablespoonful is given three times a day. This, he says, never produces unpleasant effects, and is, in his experience, superior to tincture of iodine, tincture of eucalyptus, and even to arsenic, cinchonine, and resorcine, though scarcely equal to quinine or carbolic acid and corrosive sublimate. It is, however, a simple and a very convenient remedy for out-patients in dispensary or parochial practice.

Scrofulous Tumors.

The Paris correspondent of the London *Med. Press* tells us that M. Besnier recommends that in the treatment of those soft scrofulous tumors of the neck so often witnessed, and which generally when left to themselves, or treated by incision, leave such ugly scars, an effort should be made to prevent suppuration, or at least the issue of the matter. He, himself, has obtained the most happy results from a solution of iodoform (ʒss to ʒiiss of ether). The immediate effect is pain rather sharp, and then swelling, but soon the tumor diminishes progressively, and finally disappears, leaving in its place a little hard nodule.

Paralysis Agitans without Shaking.

Dr. Beevor related several cases of paralysis agitans without tremor, in a paper read before the Medical Society of London. In these cases, fixed attitude, rigidity of the neck, with difficulty in looking up, expressionless countenance, slow delayed movements, difficulty in rising from the sitting posture, monotonous and mumbling speech, were present. The writing in nearly all the cases was wavy; retropulsion, apropulsion was frequently present. Charcot, Buzzard, and Gowers have published cases of this kind. It seems possible for paralysis agitans to run its course without any tremor being present.

Paralysis after Tonsillitis.

Dr. Prévost mentions in the *Archives Médicales Belges*, an exceptional case of paralysis of the arm following tonsillitis. An officer had a sharp attack of tonsillitis, so that scarification was necessary, but there was no exudation which might suggest diphtheria. The affection had been cured for some time, and no trace of it remained, when the patient complained of weakness in the right arm, which increased by degrees, and resulted in paralysis. After trying various remedies, the patient was cured, and no trace remained of the paralysis.

Pharyngeal Catarrh and Pepsin.

Dr. J. Fisher, of Berlin, had a patient suffering with chronic pharyngeal catarrh (*Berl. kl. Woch.*, 49–86). Various local and internal remedies were tried in vain, until finally, the patient complaining of some transient gastric disturbance, caused by too luxurious a meal, the doctor advised him to take five grains of Jensen's pepsin, which, by the way, is also recognized in Germany as the best pepsin in the market, immediately after each meal. The patient, who from the frequent medication had become averse to medicine, took the pepsin pure, one-half grain of aromatic powder being added to five grains of Jensen's pepsin, simply to preserve the latter in its dry state. The effect was remarkable. Not only the stomach improved, but after three days' use the pharyngeal catarrh also showed decided amelioration. Dr. F. then administered the pepsin in still larger doses, ten grains each, and two weeks later the catarrh had disappeared. The same remedy was afterwards tried in four more cases and with the same result, but other pepsin preparations failed.

There is one symptom that seems always to yield readily to Jensen's pepsin, viz., the peculiar dryness, of which patients suffering from chronic pharyngeal catarrh are so apt to complain. The remedy ought to be taken in its pure state, only a moderate dose of aromatic powder being added to keep it dry, and it should be allowed slowly to dissolve in the mouth.

Cauquoin's Paste.

This paste, much praised for its removal of cancerous growths, particularly those of the lip, is composed of chloride of zinc, eight parts; oxide of zinc, one part; flour, dried at a high heat, seven parts; cold water, one part. The directions for its preparation are to dissolve the chloride of zinc in the water, and, having added the oxide of zinc and the flour, rub the mass in a mortar. This compound must be used with some caution, as death has been reported from its injudicious use.

Suture of Widely Divided Nerves.

Dr. Assaky presented a thesis on this subject to the Paris Biological Society. The doctor advises that the central end be joined to the peripheral end by means of catgut sutures. Excellent results follow, even if no close approximation is possible, when the loss of substance is great. Experiments show that suture promotes and hastens regeneration. The cicatrix along the track of the sutures is found richer in nerve fibre than where no sutures are used.

Combinations of Lanoline.

O. Philipp has stated the result of his experiments as to the best modes of prescribing lanoline. With soft fats, fatty oils, and oily substances, such as pix liquida, ol. cadini, oil of turpentine, and ichthyol, lanoline mixes easily. Hard substances, as cetaceum, must first be melted, and then the lanoline stirred into the melted mass. Overheating of the lanoline must be avoided, otherwise the water separates from the cholesterin fat.

Treatment of Trichinosis.

In several cases of trichinosis in man, Fiedler has been successful in effecting a cure by the administration of one tablespoonful of pure glycerin every hour in grave cases; in less pronounced cases he advises a smaller dose hourly, as large quantities of glycerin may produce hæmoglobinuria and other toxic symptoms. It may also be given per rectum. German journals are very emphatic in declaring this agent a cure for the dreaded trichinosis.

Naphthalin as an Anthelmintic.

Dr. Coriander, of Samarkand, recommends naphthalin as a valuable economical remedy, especially in country and military practice, for worms, both tænia and ascarides. He gives children of from one to three years of age 2 or 3 grains twice a day. In the case of adults he gives from 20 to 80 grains a day in powder with sugar.

An Unrecorded Danger from Continued Large Doses of Iron.

When iron is indicated and ordered, it usually happens that its use is persevered in for a long time.

Dr. J. Strahan calls attention, in the *Brit. Med. Jour.*, September 18, to the fact that it is likely to cause intestinal concretions, and we should remember this fact.

Urticaria.

Lassar cuts short the duration and reduces the frequency of violent attacks of urticaria by 24-grain doses of salicylate of sodium, repeated every two hours until three doses are taken. It is certainly well worthy of a trial, as the trouble is undoubtedly at times a very stubborn, not to say serious one.

CORRESPONDENCE.

Paris Letter.

Curability of Cirrhosis of Liver—Diseases Common in Syria—Treatment of Fractures by Massage—Antipyrin in Infantile Therapeutics—Rabies—Iron Fork Extracted by Gastrotomy—Curious Statistics—Turpentine in Diphtheria—Oxymel of Squills in Pertussis.

PARIS, *October* 1, 1886.

EDS. MED. AND SURG. REPORTER:

At a recent séance of the Société Med. des Hôpitaux, cirrhosis of the liver and its prognosis came under discussion.

It has been generally considered an incurable disease. "Where ascites is present in conjunction with the other symptoms proper to cirrhosis, no hope of cure can be entertained, and treatment is only palliative," such are the words of Rendu, in the Dictionnaire Encyclopedique. Frerichs considers the disease fatal in the great majority of cases, and almost inevitably so when arrived at its full period of development. However, in the course of this discussion a number of cases where cure was obtained after the patients had presented all the symptoms of the disease were reported by various and able clinical observers.

Troisier reported one, of alcoholic origin, where cure was obtained, and MM. Siredey and Dumontporcelet, a similar one; in both these cases the duration of treatment was unknown. Féreol reported a case where cure was obtained after three months, Richard, one after eighteen months, and Dieulafoy, one after two years. Finally, M. Saucerotte, of Lunéville, reported a case which had come under his father's care thirty years previously, where cirrhosis had been diagnosticated by Fouquier and other eminent practitioners. The patient was under treatment about one year, and enjoyed excellent health up to the time he came under M. Saucerotte's observation, thirty years later.

At a recent séance of the Academie, an interesting communication was received from M. De Brunn, Professor in the French College at Beyrouth, on the diseases most prevalent in Syria.

Malaria comes first in rank, and is very frequently observed; it gives rise in many patients to crises of laryngeal spasm, due to acute œdema of the parts, and these accidents are most amenable to treatment by the sulphate of quinine. Next in frequency comes syphilis, which is very common among the Mussulman population. Affections and derangements of the digestive organs are frequently caused by poor food and the abuse of cheap arrack, a liquor containing from 38 to 40 per cent. of alcohol. As in most oriental countries, gravel and stone, and also affections of the eyes, particularly granular conjunctivitis, are very prevalent.

In summer a skin affection accompanied by severe pruritus, and called sweat dartre or button, causes much suffering among the poorer classes.

A new method of treatment of fractures, particularly of the radius and fibula, was recently brought to the attention of the Societe de Chirurgie by M. Lucas-Championniére. This consists in immediate and prolonged massage at the seat of fracture, without the application of any splint or other apparatus to secure immobility.

M. Championniére asserts that in many cases this has given very excellent and rapid results. In a recent case, a fracture of the radius occurring to a physician, three days of massage had proven of such benefit that he was then able to write prescriptions with the injured hand.

M. Trélat, in the discussion which followed this communication, considered that proper coaptation of the fractured surfaces, with complete immobility, was absolutely necessary for their proper union; massage and all other such methods could only serve later in reducing stiffness about the joint. He considered that three weeks in splints was generally sufficient, but would not by any means leave the fracture without any form of apparatus, as recommended by M. Lucas-Championniére and by Tilanus, of Amsterdam.

M. Moncorvo strongly recommends antipyrin in infantile therapeutics; he regards it as the least dangerous of febrifuges, and has given as much as one gram for a dose to the youngest infants. It always procures a reduction of temperature in pulmonary affections, inflammatory or otherwise.

In a recent discussion on an assertion of M. Canetolli, that rabies was sometimes of spontaneous origin, M. Dujardin-Beaumetz mentioned some curious facts in relation to the subject.

He denied absolutely the assertion that rabies is ever spontaneously developed; a dog never becomes affected with the disease unless bitten by another dog already suffering.

Since the compulsory use of the muzzle has been adopted in Berlin, rabies has been almost entirely suppressed in that city.

It has been said that rabies is almost unknown in Constantinople, notwithstanding the great number of dogs which infest that city. This is on account of their curious and well known customs. The dogs seem to be divided up into groups, each group occupying a certain quarter of the city. If any strange dog appears, or if any dog strays into the wrong section of the city, he is immediately set upon and devoured by the inhabitants of that section. So that, as dogs belonging to strangers have to be jealously guarded, there is not much danger of the introduction of rabies. In Paris there are many dogs allowed to run loose during the day, and if one becomes mad there is no impediment to his spreading the disease.

M. Pollaillon recently performed gastrotomy for the removal of an iron fork swallowed by a boatman. The presence of the fork in the stomach was clearly indicated by the deflection of the magnetic needle, in a very delicate apparatus, devised by M. Trouvé. The operation bids fair to become successful, as all indications point to speedy recovery of the patient. According to M. Pollaillon, out of seventeen cases where forks were swallowed, in seven the foreign object did not cause serious accidents, and was eliminated after formation of abscess. This case has attracted considerable attention here at Paris, where surgical operations on the stomach are not so frequently performed as in Germany.

One of the most curious statistical records recently compiled is that of Dr. Salzmann, of Essling, in Wurtemberg. He found on going over the ancient records of Essling, that in the sixteenth century the average duration of life among the physicians was 36.5 years; in the seventeenth, 45.8; in the eighteenth, 45.8, while at the present time the physicians of Wurtemberg reach the very favorable average of 56.7 years. It would appear that this very great increase in longevity was due to the disappearance of the pest, and the great diminution in the number of typhus epidemics. The black death, or black pest of the fourteenth century, decimated the practitioners of that epoch. Guy de Chauliac suffered from it twice and recovered; Chalin de Vinario succumbed.

At the Congrès General for the Advancement of Sciences held this year at Nancy, M. Delthel spoke somewhat in detail of his treatment of diphtheria by inhalation of the vapor from spirits of turpentine, and swabbing the throat with the same product. He has had 126 recoveries in 134 cases. His treatment is very simple: Near the patient's head and in different parts of the room he places large platters containing common spirits of turpentine, and uses the same liquid over the membranous patches with the swab. Incidentally he called attention to the notable increase in the mortality of this disease; in Paris there is a yearly mortality of 2,000 from diphtheria, while in Saxony 20,000 people have perished from the disease in the space of four years. He is of opinion, and his views in this respect were sustained by MM. Verneuil and Bouchard, that there is a similar disease among poultry, and that in certain cases this might lead to the spread of the disease.

M. Netter, at the same Congrés, vaunted the excellent results obtained from the administration of oxymel of squills in whooping cough. To nursing infants he gives from forty to sixty drops daily, in divided doses. To a child two years of age he gives four or five teaspoonfuls in the course of one hour, and then no more until the following day at the same hour. For older children he increases the dose to six or seven teaspoonfuls. Under the use of this remedy the cough becomes softer, and the number and duration of the spasms rapidly diminish. * * * *

Charms and Superstitions.

Eds. Med. and Surg. Reporter:

In the Reporter for August 7th, is an article on "Charms and Superstitions," etc. If you desire anything more in that line, I can give a few items of superstitions and charms, practiced by some of the people in this corner of the foot-stool.

To carry an axe on your shoulder through the dwelling house is a sign your next child will be a boy. To carry a "horse chestnut" in your pocket, will not only prevent, but actually cure "piles." To carry some of the fruit of the coffee-nut tree in your pocket will prevent an attack of cramp colic. Wearing a brass ring on the little finger of the left hand will cure and prevent rheumatism. To repeat a few words, said to be contained in the Bible, and blowing the breath on a burn three times, will cure the worst case. Wearing a leather shoe-string around the neck will prevent whooping-cough.

The persons practicing the above superstitious folly are well known to myself. Besides that which has been enumerated above, there are quite a number of other charms believed in. With the exception of this superstition, the individuals otherwise seem reasonably sensible. But these things having

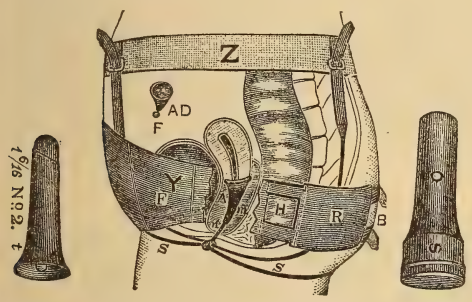
been handed down from generation to generation are firmly believed in; and the skill of a physician who is the seventh son of a seventh son, is, in their estimation, beyond all doubt, perfect. A READER.

Morea, Ill.

NEWS AND MISCELLANY.

Staufer's Gynecological Instruments.

This series of hard-rubber instruments has been advertised in this journal for a period of fifteen years. The series now comprises 200 styles and sizes of womb-supporting and womb-examining instruments.



Single, $2.50 — Spring Stem Cup on Y, $6.00; " " " " Z, 5.00 — Encased, $12.00

The engraving represents a spring stem and internal yielding stem cup supporter, on abdominal supporting belt. Fig. *y* on the left a hard-rubber speculum and conductor, flesh color inside, showing the vaginal portion of the uterus as plainly as if located externally. On the right the series of 4 graded speculums and conductors in a hard-rubber case. Whole weight but 10 ounces. The hard rubber parts are exchanged at cost (less repair if needed), throughout the catalogue, without limit of time. The same guaranteed. Please send for catalogue, rules and limit of guarantee.

Instruments and catalogue obtained by addressing MEDICAL AND SURGICAL REPORTER office.

Recent Therapeutics.

The question is often asked us by correspondents, Which is the best work on Therapeutics? The query cannot be answered by giving a single title. Therapeutics may be studied as a classification of drugs with reference to their effects in disease.

From this point of view we give the preference to Dr. T. Lauder Brunton's work, "Materia Medica and Therapeutics." On the other hand, the reader may prefer to have a classification of diseases, with a synopsis of their most appropriate remedies, and a statement of the treatment adopted by the most eminent living physicians. To such a reader we commend the series entitled *Modern Therapeutics*, published at the office of this journal, in four volumes, as follows: I. Modern Medical Therapeutics, by Dr. G. H. Napheys, $4.00; II. Modern Surgical Therapeutics, by the same, $4.00; both revised to a late date. III. Therapeutics of Diseases of Women, by Dr. Wm. B. Atkinson, $3.00. IV. Therapeutics of Diseases of Children, by Dr. Joseph F. Edwards, $3.00. The volumes are sold separately, at the prices named (in cloth), and the unusual offer is made that if they are not satisfactory, and are promptly returned, the price will be refunded.

Wyeth's Vaccine Farm.

One of the questions set down for discussion at the recent conference of State Boards of Health was, "Should Vaccination be made Compulsory?" Such a question, one would suppose, should be unhesitatingly answered in the affirmative, when we realize, as we do, what an absolute protection this trivial operation affords against the terrible ravages of small-pox. But there are those who say that vaccination may be potent for much evil, and there is good ground for this fear. It is impossible now-a-days to do all our vaccinating with absolutely irreproachable human lymph, and in using that from the cow we are not always sure of what we are getting. The firm of John Wyeth & Bro. have recently started what may be truly called a *model* vaccine farm. We have personally inspected this farm, and we can honestly say that we have never seen a more perfect establishment. The quarters for the vaccinated heifers are perfectly ventilated, and are so arranged that they can be, and are, kept scrupulously clean. The farm is on such an extensive scale that the Messrs. Wyeth can supply an almost unlimited demand for lymph, and we feel no hesitation whatever in recommending in the strongest terms their product to the profession.

Force of Growing Plants.

The force exerted by growing plants is very great. Fungi are composed of soft tissues, yet a growing mushroom has been known to lift a large paving stone. The rootlets of pines and cedars growing on the sides of rocky declivities penetrate narrow crevices in the rocks, and finally by their

growth loosen huge masses and send them tumbling down the cliff. Years ago President Clarke, of the Massachusetts Agricultural College, put a pumpkin into harness and demonstrated that it was capable of lifting thousands of pounds. In a cemetery in Hanover a seed germinated in a crevice beside a tombstone which contained twenty cubic feet. The seedling, now a small tree, has lifted the stone over five inches. Not the least wonderful of phenomena of this class is the force exerted by the radicle of the germinating plant. Darwin has demonstrated that it exerts a force, which in proportion to its size, is astonishing. This force the plantlet utilizes in sending its root into the soil, and the strangest part of the strange phenomenon is that the little soft radicle is capable of penetrating soil very much harder than itself.

Sir Joseph Lister's Operations.

The foreign correspondent of the *American Practitioner and News*, who has watched Sir Joseph Lister operate, says that he is excessively slow, and is by no means careful in the details of antisepsis. He has given up the spray entirely, and is now using for dressings gauze and cotton impregnated with a new antiseptic. The nature of this is at present a secret. The bold Kentucky correspondent confesses that he "had the cheek to ask Sir Joseph for information on the subject, when he very politely replied that he was sorry to have to decline giving it to me; that it was yet a secret, and he wished to keep it as such until he was fully satisfied as to its efficacy, when he would make it known to the profession. He said that it had been on trial in his wards for many months, and that so far he was greatly pleased with it."

Fees for Obstetrical Practice.

The *American Lancet* says:

What fee should be charged a wealthy man for attendance upon his wife in confinement, more than four hours of day-time being thus consumed, and several visits made the patient during convalescence, by a practitioner of more than 25 years' experience, and occupying one of the most prominent positions among the medical profession of Detroit? Such was the question put to us the other day by another Detroit physician. Our guess was far too high, and yet we estimated the time at about plumber's prices. We doubt if any of our readers would nearer approximate the truth. As a fact, we are ashamed to state the sum. It is no wonder that so many of the physicians of Detroit are poor.

Fasting in Russia.

It is stated in the *Sanitary World* that the Holy Synod, in St. Petersburg, has decided that Russian soldiers in future must observe Lent in the most rigorous way. They will have to fast not only during the four "Great Lents" yearly, but also every Wednesday and Friday, and the six great days of prayer and repentance. This is the calculation: The Great Lent (of Easter), 79 days; Petroffki Lent, 20 to 50; Usspenski Lent, 17; Filippoffski Lent, 39; six days of prayer and repentance, 6; 31 Wednesdays and 31 Fridays, 62; total, 170 to 200 days, on which dates neither meat nor fish (during the Easter Lent), nor eggs, nor milk, nor even sugar, is allowed. The officers assert that the physical strength of the soldiers must inevitably suffer from the new regimen.

Morals and Massage.

English journals are exposing some of the immorality which is said to be associated with the practice of massage by professionals. If the stories are true, many of the establishments are little better than houses of ill-fame. One journal says: "There is only too much reason to believe that the professional *masseur* exercises his or her skill in the direction of exciting the sensual feelings of the patients, or rather victims, and that the success of the professional rubber is closely connected with effects on the system in this direction." Physicians in this city are often informed of similar practices occurring in such establishments here; and doubtless there are none who do not take proper precautions in recommending massage.

Ambiguous Charity.

The other day a grand ball was given at the Hôtel Schweizerhof at Lucerne, in aid of the sufferers from cholera in Italy. Several thousand francs, the proceeds of the entertainment, were handed over to the Italian Relief Committee, more, it is said, to the advantage of Switzerland than of Italy. In the words of an "Indignant Italian," the 'impression is thus made general throughout Europe that Italy is sore stricken with cholera, and travelers are afraid to cross the Swiss frontier, to the serious detriment of the Italian hotel-keepers and tradesmen, and to the corresponding gain of the astute

Switzers, while the subalpine lakes from Lago Maggiore to Lago di Garda were never healthier or more attractive."

Decay of Bakers' Teeth.

A valuable lesson in the vigorous and frequent use of the tooth-brush is to be learned from the following extract from the *Independent Practitioner*. It says that one of the most convincing features in favor of the chemico-parasitic theory is its ability to account for the most diversified phenomena of decay. A striking proof of this is furnished by an article on the above subject from Prof. Dr. Hesse, in the *Deutsche Monatsschrift*. Hesse finds that bakers suffer to a surprising extent from decay of teeth, affecting principally the labial surfaces. He attributes it to the fact that bakers constantly breathe in flour, which is deposited upon the surfaces of the teeth, where it speedily ferments, after being converted into sugar by the diastase of the saliva.

The Value of Nostrums.

The New York *Evening Post* says: "What a commotion there would be among our patent-medicine venders if the New York police followed the example of the Berlin police, who are continually issuing warnings to the public, of which the following is a specimen: "The tradesman, Paul Heider, of this city, Anklamer Street 28, is selling, under the name of 'Harz Mountain Tea,' a mixture of lavender flowers, sassafras root, peppermint, and several other plants, weighing fifty grammes. His price is fifty pfennigs, and he advertises it as a remedy. Official analysis has shown that the real value of one of these packages is hardly ten pfennigs.'"

A Parisian Mystery.

An example illustrating the necessity of post-mortem examination of the bodies of all persons who have died under suspicious circumstances, or from any unknown cause, has recently occurred in Paris. The dead body of a little girl was found in a street (Rue Vertbois) about a week ago, and as no person came forward to claim it, this of course gave rise to all sorts of suspicions as to the cause of death. This, however, was soon cleared up at the morgue, where at the necropsy Dr. Descouts discovered in the trachea of the child an intestinal worm (the ascaris lumbricoides) fifteen centimetres long, to which he attributed the cause of death by asphyxia.

A Short Method of Cure for all Diseases.

The latest religious sect in Russia has been founded on the dogma that it is a sin to let a fellow-member suffer the martyrdom of disease. Accordingly, when anybody falls sick, one of the believers goes to him and chokes him to death. The person commissioned for the deed is clad in red clothes, and is known as "the red death." Unfortunately they do not confine their delicate attentions to the members of the sect alone, but impelled by a broad charity, seek to cure in their peculiar way every one, whoever he may be, who has the misfortune to become ill.

Hopeless.

Sir Astley Cooper used to relate the following anecdote of an Irish candidate before the Examining Board of the London College: "What is a simple and what is a compound fracture?" asked the examiner. The reply was: "A simple fracture is when the bone is broke, and a compound fracture when it's all broke." Sir Astley asked him what he meant by "all broke." "I mean," he replied, "broke into smithereens, to be sure." I ventured to ask him what was "smithereens." He turned upon me with an intense expression of sympathy upon his countenance, "You don't know what is smithereens? Then I give you up!"

Death Following an Application of Collodion.

A death is reported in France from the application of collodion to the face of a woman suffering from small-pox. The design of the application was to prevent pitting. Suppuration took place under the mask of collodion, and the patient died after great suffering. As the small-pox was discrete and uncomplicated, and the autopsy showed no visceral lesions, the fatal termination would seem to have been due to the injury resulting from the collodion.

Reorganization of the Jefferson Medical College.

It has been announced, we believe correctly, that there will be a reorganization of the Jefferson Medical College. The office of Dean will be abolished, and those of President and Secretary be established—Professor J. M. Da Costa, M. D., to be President, and Professor J. M. Holland, M. D., to be Secretary of the Medical Faculty. Professor Roberts Bartholow, the present Dean, will resign.

The Importance of Cleanliness.

In the annual discourse before the Massachusetts Medical Society at its last annual meeting, Dr. R. M. Hodges says: "Dirty finger-nails may communicate a fatal poison, through the trivial operations of surgery which every physician undertakes to perform, or inaugurate the 'private pestilence' which still sometimes follows in the track of the obstetrician."

Goodell's "Lessons in Gynecology."

A new, enlarged, and thoroughly revised edition of this standard work will be published at the office of this journal next January. As the last edition was rapidly exhausted, orders for the next one should be sent in early to Dr. D. G. Brinton.

Electrical Apparatus.

An electrical battery is now so indispensable an adjunct to a physician's outfit that his office is unfurnished without one. We happen to have quite a variety on hand, of different styles and prices, all new, and by addressing this journal, a physician can supply himself with one at a large discount.

Items.

—Speaking of *purgatives*, Prof. Bartholow told of an old soldier who always carried about him a bullet, which he had used for *forty years* as a cathartic. It acted by its weight.

—Dr. O. W. Holmes said in his address to the students of Edinburgh: "Literature was a good staff for walking with, but not a good one to lean upon. From Coleridge he had learned that every literary man should have some fixed and regular occupation."

—In a case of *infantile eczema*, Prof. Bartholow, besides directions given as to diet, placed the child (aged two years) upon tinct. belladonnæ, gtt. v, ter die, or sufficient to cause dryness of the mouth. The object in view is to affect the cutaneous circulation, and thus bring about the desired result.

——The latest issues of the Physician's Leisure Library embrace "Spinal Irritation" by William A. Hammond, M. D.; and "The Modern Treatment of Eczema," by H. G. Piffard, M. D. Both these monographs sustain the high position which their authors have already obtained among American medical writers.

—The *Weekly Medical Review* (Sept. 25) says that the sorehead opponents of the Congress who have been abroad this summer misrepresenting the same, had better, like the Irish tramp, apply to their respective lying-in-hospitals for quarters. It's the right place for them, as they have been lying out of the country these three months.

—Doctor ——— called at a house, and was met at the door by a little daughter of the family. He asked her to tell her mother that the doctor had called. The child went up stairs and soon returned. "Did you tell your mamma?" asked the doctor. "Yes." "And what did she say?" "She said, 'Oh, pshaw!'"

—According to the *Schweizer Handelscourier*, September 3, 1886, on August 31 a Swiss Asylum for Epileptics was opened in Rueti, near Ries-Zurich. It is the first institution of its kind in Switzerland. The number of beds is 50. It is almost superfluous to add that all the beds were filled on the very first day. The institution is directed by Dr. Koelle, formerly of Stetten.

—Dr. Geo. T. Stevens, of New York, has received the prize of the Royal Academy of Medicine of Belgium, for the best essay on "Elucidating the Pathogeny and Therapeutics of the Diseases of the Nervous Centres by Clinical Facts and Experiments." Of all the essays submitted, only his will be published by the Academy.

—The police authorities in Berlin have published an order requiring physicians to give written notice to the sanitary board within twenty-four hours after the diagnosis of the disease, in every case of puerperal fever, whether followed by death or not. The name of the midwife in attendance is also to be given.

—A correspondent of the *North Carolina Medical Journal* describes Mr. Jonathan Hutchinson thus: "He seems scarcely more than fifty years old, is tall, rather thin, and round-shouldered, has dark hair and dark complexion, an intelligent but homely face, and might pass himself off at the State Fair or anywhere else as a North Carolina farmer, without the slightest fear of suspicion."

QUERIES AND REPLIES.

OINTMENT FOR SYPHILITIC ULCERS.

EDS. MED. AND SURG. REPORTER—

I have a patient who contracted syphilis some years ago, and now whenever his skin is bruised or lacerated, the healing process is very slow. What can I do? M. D.
Iowa, October 15.

Ans.—A most admirable ointment in such cases is—

Ung. Hydrarg. nit.,	3j.
Cosmoline,	3vij.
M. & ft. ung.	

Pallas Syringe."

[From the *London Medical Record.*]
"It is a useful Instrument, and will be a formidable rival to the ordinary vaginal douche,"

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

THE MORTALITY OF THE SEXES AT DIFFERENT AGES.

BY THOS S. SOZINSKEY, M. D., PH. D.,
Of Philadelphia.

The mortality statistics of the U. S. Census of 1880 are very far from being complete, except for a few cities, yet they are not without value. From their extent they afford us excellent data for many interesting studies. To gather from them some light on the subject of the mortality of the sexes at different periods of life is my purpose at this time.

However incomplete the statistics in question may be, it is pretty certain that they are about as complete for one sex as the other, not only as regards number, but the age at death. The truth of this statement admits of little doubt; still it is proper to say that Dr. Billings is of the opinion that probably the "deficiency in the returns of deaths of females is somewhat greater than for the males." Whether the year of age given is correct is another matter, but in respect to it I may say that by dividing life into periods of five years each the returns may be taken as moderably accurate for both sexes.

The whole number of deaths reported as having occurred during the census year was 756,893, of which 391,960 were males and 364,933 females. Hence, of the deaths reported 51.78 per cent. were males and 48.22 females.

As need hardly be said, the census returns present a very unequal number for each age. Thus, while the number of deaths returned as of persons under five years was 302,625, the number between five and ten years was only 43,093. In the various periods of five years after the tenth year, however, the number of deaths returned do not differ vastly. Between ten and fifteen the number returned was 22,915, and at no period was it more than 7,000 over this up to the period ending at eighty, for which it was 22,352, except the two periods between twenty and thirty for which the returns were 39,355 and 33,132.

In order to render the relative mortality of the sexes, at different periods of life, more obvious, I have reduced the census returns to percentages as indicated in the following table:

Age.	Males.	Females.
Under 1	55.28	44.72
1	53.24	46.76
2	52.56	47.44
3	51.59	48.41
4	51.07	48.93
Under 5	54.12	45.88
5–10	50.21	49.79
10–15	49.00	51.00
15–20	44.59	55.41
20–25	45.85	54.15
25–30	45.26	54.74
30–35	45.77	54.23

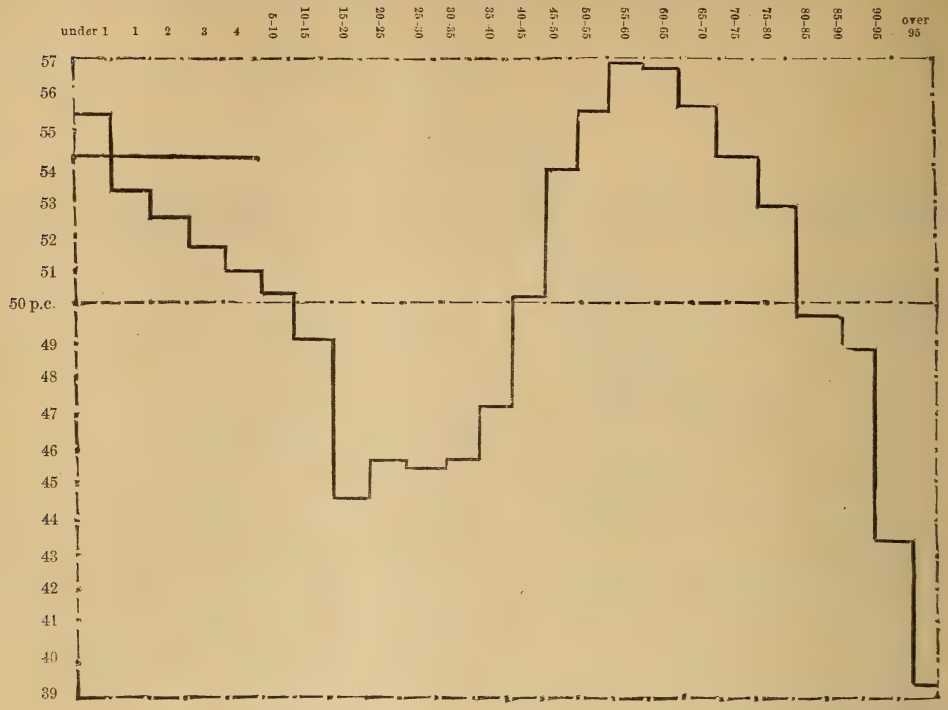
The above table of percentages of deaths of the sexes at different ages is very clearly presented in the accompanying diagram:

Now, it is certain that there are more male than female children to begin with. The

DIAGRAM SHOWING THE PERCENTAGES OF MORTALITY OF THE SEXES AT DIFFERENT AGES.



The **heavy** line shows the p. c. of deaths of males of different ages. The p. c. of deaths of females of different ages is implied.

*This line shows the p. c. of deaths of males under 5 years.

male births exceed the female by four per cent., perhaps more. Hence there being more male than female children one would expect the deaths of males to out-number those of females. But beyond doubt a greater percentage of males than of females die in childhood. On looking at the diagram it will be observed that over fifty-four per cent. of the deaths of children under five years are of males. And from the first up to the fifth year it would seem that the males suffer less and less. Dr. Billings is partly correct and partly incorrect in saying that the "excessive death-rate of males occurs chiefly at the earlier ages." It appears that even in the very immature sex makes itself felt. Bacon was but approximately correct in his declaration that in "all young creatures males are like females."

From the fifth to the tenth, or, I might say from the fifth to about the fifteenth year, the deaths of males and females are nearly equal in number. A similar statement applies in the period between forty and forty-five, and also in the period between eighty and eighty-five. In England the deaths of the sexes appear to be equal from five to ten years and from thirty-five to forty-five, as will be observed by consulting the following table of the yearly deaths to the 1,000 living of each sex at the ages indicated:

Ages.	Males.	Females.
Under 5	74	63
5–10	9	9
10–15	5	7
15–25	8	9
25–35	10	11
35–45	13	13
45–55	19	16
55–65	32	29
65–75	69	61
75–85	150	137
85–95	303	281
Over 95	452	452

The construction of this table, I may remark, is, of course, different from that of the one given above. The United States census statistics, both as regards ages and the deaths, are so inaccurate that it would be waste of time to cipher out a similar one.

From the period of puberty forward to about the fortieth year the deaths of females are greatly in excess; girls between fifteen and twenty are particularly unfortunate. It is at this period, I may say, that consumption of the lungs is so much more destructive—twice as destructive—to females than to males, as I have pointed out on another oc-

casion (MEDICAL AND SURGICAL REPORTER, January 1, 1881).

After the thirtieth year the mortality of women lessens and continues to lessen up to the period between the fiftieth and sixtieth years of age, at which time it is at its minimum, relatively speaking.

The figures given possibly do not express fully the excess in the mortality of females, aged from fifteen to forty. The male population of such age is considerably more increased than that of females through immigration. Still, I believe, the female population is as great, or even greater, than the male from the fourth up to perhaps over the twenty-fifth year.

From the fact that there is an excess in female mortality between the fifteenth and fortieth years or so, many, and among them Dr. Billings, connect it with child-bearing, but it is doubtless an error to attribute it more than in small part to the mishaps attendant on the performance of this great function. Child-bearing is getting to be a terrible bugbear to humanity!

At this point I may remark that there is nothing in the figures given to indicate that women are in any special danger of losing their lives about the time commonly spoken of as the change of life. The contrary, indeed, is the case. The actual figures do not show an excess of deaths of females from the fortieth to the fiftieth years of age; there is a gradual fall in the number of deaths per year from the thirtieth forward to the fiftieth. From the forty-fifth year forward to the seventieth, but particularly between fifty-five and sixty-five, women fare better than men.

After the sixty-fifth year, the percentage of the deaths of males is less and less until the final period, running from ninety-five, is reached, when of all the deaths a trifle less than forty per cent. only are of males.

In both extremes, youth and extreme age, the female has the surer tenure of life. The remark that she is the frailer vessel, is only in part true. Against the various forces which tend to destroy, she resists the better, save during the five-and-twenty years between fifteen and forty.

SOME OBSERVATIONS DURING TWO YEARS' RESIDENCE AT COLORADO SPRINGS, COLORADO.*

BY J. T. ESKRIDGE, M. D.

I will endeavor, in as brief a space as possible, to make some practical remarks concerning Colorado Springs as a health resort for consumptive patients especially. For what I shall have to say of the climate I shall rely mainly on my own observations, made during the two years that, as an invalid, I have resided there. In regard to the effects of the climate on phthisis, I will try to sum up the results of the experiences of the principal physicians of the place, and give them, together with what I have observed. I am not ignorant of the fact that you can find over-painted descriptions of Colorado climate. So you may of every other climate that is supposed to have a beneficial effect on lung troubles. To such a degree have the climatic virtues of different places been lauded, that disinterested physicians have come to have but little more confidence in the greater portion of the statements in articles written by physicians who reside and practice at these various health resorts than they have in the exaggerated accounts of the healing powers of some patent medicine; and as the nostrum is praised simply because it pays, so physicians do not altogether escape suspicion or even censure of being influenced by mercenary motives in their comparisons of the relative advantages of different climates. The truth is, it is very difficult not to allow one's self to become over-enthusiastic concerning the merits of a place in which you find so many who were failing rapidly before leaving their homes able to enjoy life, live in the open air, and frequently resume business again. That I may escape any suspicion of being influenced by a mercenary motive in writing this paper, I will state that since I have been at Colorado Springs I have done no general practice, nor do I intend to resume it there. From time to time I have had cases of lung trouble referred to me by Eastern physicians, but I have invariably refused to attend them. I am glad to have this opportunity to say that there are a number of good physicians residing there. I have never before been in a place of its size where so much intelligence and talent in the medical profession was to be found. The greater portion of the physicians who reside there have been compelled to go to Colorado on account of their health. Most of them are graduates of some of the best medical colleges East. I am sorry to have to say that you will also find a number of irregular physicians there.

Climate.—I wish to remark, in prefacing this subject, that the longer one has resided in Colorado, the less certain he is regarding

*Read before the Philadelphia County Medical Society, September 22, 1886.

weather prognostics there. For convenience sake, the weather may be divided into two seasons, the wet and the dry. The former usually begins in April and ends in September or October. From October to April, as a rule, there is no rain. During a large portion of the wet season it is the rule to have daily showers in the early part of the afternoon, lasting from half an hour to an hour, the remainder of the day being clear. In the latter part of June and the early portion of July of the present year, there was a dry spell of several weeks' duration, with almost no rain at all. Most persons who visit Colorado are prepared to expect the daily showers, during the rainy season, but what they are not prepared for, and what not infrequently makes many suspicious of the reputed dryness of Colorado weather, is the occurrence, once or twice annually, of rainy spells of weather, lasting two and sometimes three days. During a portion of these times it rains as hard as I ever saw it along the Atlantic coast. So much for the rainy season. I have seen it stated that no rain falls there from the last of October till March; yet, during last winter I remember two light showers. They did not last long, nor did much water fall. Some persons who had resided in Colorado Springs for several years told me that they had never seen rain there before during the winter months. I should not consider these showers of sufficient account to deserve mention, were I not trying to give as accurately as possible my observations of the weather there for the past two years. No rain fell in the winter of 1884–85. During the winter repeated light snows fall, but they do not lie on the ground long, and evaporation is rapid and the soil porous, so that they disappear without leaving the ground damp for more than a few hours after the snow is gone. While the snow is rapidly thawing in the hot sun, but little water is found on the ground, so that the days and weeks of terrible sludge so commonly experienced in many portions of the country are almost, if not entirely unknown in Colorado Springs. It is in the cool, dry weather that the air has the most invigorating effects. It sometimes may be said to be crispy and exhilarating. The warm season is much shorter than we find it in Philadelphia. Spring is late; in fact, this season seems to be largely dispensed with, and the change from cool wintry weather into mild summer heat is not uncommon. The years that I have been in Colorado, cool weather has begun the latter part of August, although it is frequently quite warm in the middle of the day until late in September or the beginning of October. The warm season is but little over two months' duration. During this season the thermometer in the shade may rise from 90° to 100°, but, as a rule, only for a few days in succession. The summer just past seems to have been an exception in this respect, for we had a spell, of one or two weeks, of quite hot weather. During August of 1884 (the time when I first reached Colorado Springs), and the summer of 1885, I did not experience a night that one or two blankets were not necessary. In the hot, dry spell of July of the present year there were several nights that I could not endure a single blanket. From my experience, I should say that it is the exception not to find comfortably cool nights throughout the summer in Colorado. Evaporation is so rapid that the heat is much less oppressive than we find it at the same temperature along the Atlantic coast. I never have found any difficulty in keeping comfortable on the hottest days whilst I was sitting quietly in the shade. The weather rarely gets very cold much before Christmas. Last winter no very cold weather was experienced until the first of January. The coldest weather occurs during January and February. The average temperature during these months is not very low (from 25° to 30°), but occasionally the thermometer drops to 20° or 30°. As the heat is less hard to endure, so the cold is less chilling and piercing in a dry than in a damp atmosphere. One will have to visit, in the winter, Colorado or some other place with a similar climate, and experience for himself, before he can realize fully, the difference in temperature between the shade and sun, even on the coldest winter day. During the winter, with the sun shining brightly, a thermometer exposed to the direct rays of the sun and protected from the wind will rise to 100° to 110°, whilst the the temperature in the shade, probably not four feet distant, will be below 30°. On several occasions, in midwinter, while I have been sitting in the sun, I have been compelled to use an umbrella for protection, the shade temperature at the time being sufficiently cold to freeze. One of the great advantages of Colorado climate in the winter is the amount of time that invalids can be in the open air, although they may not be able to take much exercise. During the month of February of 1885, there were only three days that I was unable to sit in the open air, with entire comfort, from about 10 a. m. to 3 p. m. The hours of sunshine in

Colorado, during the fall and winter, double, and probably treble, those along the Atlantic coast. The meteorological records, where three observations were made daily, show only three cloudy days for some winters. The observations, I have no doubt, are literally correct, but somewhat deceptive, if we were to understand by them that all the days but three of an entire winter were bright and sunny. At the hours when the observations are made the sun may be shining, and twenty minutes after it may be cloudy, as it frequently is. These changes the records do not show. Observations which, when completed, will show the hours of sunshine each day for the entire year, are being made now at Colorado Springs, by means of the sun thermometer. I admit that an entire cloudy day, during the winter and fall is rare, but there are a number of raw and partially cloudy days that are too cold and disagreeable for invalids to be in the open air, unless they are strong enough to exercise sufficiently to keep themselves warm. Besides, there are some windy days that keep the weaker invalids in doors. A few words in regard to sudden changes of temperature. I have not infrequently seen it stated, by physicians, that in selecting a climate for consumptive patients we should choose one that is dry, free from high winds and great and sudden temperature changes. If you will reflect, you will realize that where there is but little moisture in the atmosphere there can be but a correspondingly small quantity of the solar heat retained by it, so that after the sun has been shining for a number of hours, and sets, or is hidden suddenly by thick clouds, there must be necessarily a sudden fall in temperature. The sudden changes in temperature may be attended by considerable wind. So common and sudden are these changes in Colorado during the spring months especially, that no one who is prudent travels far from home or shelter without being prepared for such emergencies. You will find that when you have decided that your patient will do best in a dry climate, you must see to it that he is prepared, by a sufficient amount of strength, and good warm underclothing, to endure sudden changes of temperature, if he expects to live much in the open air throughout the year. Of course, if a patient is careful to always be where he can readily obtain shelter, he may not experience much inconvenience from the variations in temperature. Another point: a place that has a dry climate with a loose, porous soil, must of necessity have considerable dust stirring during the windy days. A dry climate with a mild equable temperature is a thing that does not exist. Again, in high altitudes the air is more rarefied than at sea-level, and in consequence a greater amount of breathing capacity is necessary for a person to breathe with ease and comfort. For the reasons that I have stated, consumptive patients, with little breathing room (unless it can be increased), or in the last stages of this disease, almost invariably do badly in dry mountainous regions, and die sooner than they will at low altitudes.

The question is often asked, How are persons in apparent health affected on going to an altitude of six thousand feet? I do not believe that persons in a good state of health experience any unpleasant sensations if they are careful not to exercise much on first reaching such an elevation, but the majority of persons visiting Colorado often make the mistake, on first arriving there, of exercising as much, or even more, than they were accustomed to do at sea-level. The consequence is, that many such are troubled with irritable heart, shortness of breath after walking, and, what is more common, especially in persons beyond the age of forty, a full sensation in the head, a dull feeling in the ears, with some lessening of the acuteness of hearing. In about two weeks, such persons, if they have not continued to take too much exercise, apparently resume their normal condition. I have made a number of observations on the acuteness of hearing in persons who have lived some time in Colorado, and these have led me to believe that this sense is not so acute as we usually find it in persons living in a damper climate. This will be easily accounted for, when we study the effects of the climate on exposed mucous membranes. These are, briefly, dryness, hyperæmia, inflammation, and thickening. The dust, wind, and dry atmosphere undoubtedly are the potent agents in producing these changes. Conjunctivitis, nasal and naso-pharyngeal catarrh, are very common. As a rule, there is not much discharge, the catarrh being of a dry, irritative character. The inflammation usually extends into the Eustachian tubes, and involves the middle ears. The larynx does not escape, and an occasional hacking cough is not infrequent in persons who are otherwise apparently well. From what I have gleaned from the experiences of other physicians, as well as what I have observed, I think that all catarrhal affections of the air-passages attended with much discharge are benefited, usually, on going to Colorado. My experience has been—

and this is in accord with that of most of the physicians with whom I have conversed on the subject—that dry, irritative catarrhal conditions of the upper air-passages, and of the middle and external ears, are made worse by residing in Colorado. It seems to be the almost unanimous impression with physicians whose opinions are entitled to consideration, that acute inflammations are sharper, and run a more rapid course, with, I think, less tendency to chronicity, than what we find of the same troubles at sea-level. The physician who is sending patients suffering from phthisis to Colorado is desirous to know what cases most probably will do well there, and what ones he ought not to send. In my opinion, no positive information that will avail in every case can be given. Some, apparently the most desperate, do well, and on the other hand, others, which he may have many reasons to believe will be greatly benefited, grow steadily worse, or fail to improve. In trying to give some information that may help the physician to decide, I shall ignore most of the different varieties of phthisis as usually classified. I do this mainly because phthisis is studied clinically rather than pathologically at most health resorts. It must be exceedingly rare that a post-mortem examination can be obtained on phthisical cases that die at Colorado Springs, for I have not been able to witness one there. Before endeavoring to specify certain classes of cases for Colorado climate, I wish to state that the physicians there are unanimous in their testimony to the fact that a prolonged residence causes an increased expansion of the chest. I am informed by some of the most careful that the circumference of the chest, on full inspiration, increases from one and a half to two inches during the first year. I think I am justified in saying that consumptive patients, in the last stages of the disease, especially if weak and nervous, or those who have in addition to their lung trouble an irritable, weak heart, due to valvular lesion or a weakened heart muscle, should not be sent to Colorado. An irritable heart caused by poor nutrition rapidly passes away as the general health is improved. Theoretically, there are two classes of cases that should not be much benefited, if at all, by residing in Colorado; one is plastic bronchitis, the other fibroid phthisis. Of the former, I know of only one physician who has a case. It has not been under his care long, but apparently it is doing well. It is well known that patients suffering from fibroid phthisis may live a long time in damp climates and at low altitudes, especially if the climate is mild. But they do not get well; neither do they in Colorado. There they live comparatively comfortable for a number of years, taking much out-door exercise. The quantity of expectoration is greatly lessened, and its character improved, but increase in fibrous tissue goes on. From the irritative nature of the atmosphere there, we should expect that the increase of fibrous tissue would be more rapid than in a milder and damper climate. It is difficult to say whether the benefits derived from the lessened quantity of secretion, the aseptic condition of the atmosphere, and probably less tendency to bronchiectasis, do compensate for the irritative effects of the atmosphere. I have been informed, by one of the best and most experienced physicians of Colorado Springs, that he never has known a case of fibroid phthisis to terminate there by the development of tubercles. What the climate seems to offer in these cases is comfort, or amelioration of the effects of the disease—not a cure, and probably not as long a period of life to the patient. I have now to consider cases for which, if other things are favorable, there is little doubt about their being benefited by the climate of Colorado. The early hemorrhagic cases appear to do the best. It is almost if not the unanimous opinion of the physicians there, that the climate of Colorado is not only not productive of pulmonary hemorrhage in phthisis, but that these hemorrhages are less frequent in a given number of cases than they are found to be along the Atlantic coast, or in the States near the great lakes. I wish to emphasize the fact that these cases must lead necessarily a very quiet life during the first period of their residence in Colorado. It is obvious that if a case that is liable to bleed on slight exertion were to go there and exercise much before the ulcerated portions of the lungs had healed, hemorrhage would result, and probably to a greater extent than it would have done from the same amount of exercise at sea level. The tendency for ulcerated surfaces exposed to an aseptic atmosphere is to heal, and for this reason hemorrhages in the early stages of consumption are arrested. I have observed that pulmonary hemorrhage is rare there in persons who are prudent. In nearly every instance where pulmonary hemorrhage has occurred—and my own case is not an exception—the patient has had himself to blame for the bleeding. I will say nothing of the influence of the climate and altitude on the production of pulmonary hemorrhage in consumptive per-

sons whose lungs contain large cavities, and who are in the last stages of the disease, for such cases should not be sent to Colorado. The effects of the dryness and aseptic condition of the atmosphere are clearly seen in lessening the secretion in cases where expectoration is abundant. Bronchial phthisis and the so-called catarrhal pneumonias do well. All those cases of phthisis in the incipient stage, provided the temperature is not too high, and the decided fever process is not kept up too long, improve rapidly. Persons suffering from phthisis may have a moderate rise of temperature, extending over a prolonged period, and yet improve, in Colorado. The fact that a person has a small cavity in the lung should not prevent his going to a high altitude, provided there is a large portion of healthy lung, and the patient is not too greatly reduced in strength. All those cases embarrassed by conditions favorable for the development of tuberculosis, as indicated by heredity, poorly expanded chest, anæmia, loss of flesh, and often extreme weakness, usually receive great benefit from a *prolonged* residence in Colorado.

In this connection I wish to say a few words concerning heart troubles as influenced by the climate and altitude at Colorado Springs. We are told by some writers that all heart affections are increased by the altitude there. To suppose that because a person has a valvular lesion of the heart, he, in consequence, will be unable to live comfortably at an altitude of 5,000 or 6,000 feet is an error. I have seen a number of cases of valvular lesion of the heart there, the physicians having been kind enough to allow me to study their cases. I know of a few who have valvular lesions, and who work daily, without experiencing any difficulty. One of these is a poor woman, who works very hard, and is not aware of her heart trouble. One patient, Dr. T., has well marked mitral regurgitation, and suffers from shortness of breath and cardiac asthma, when at Colorado Springs, but when she returns to her husband's ranch in the mountains at an elevation of about 8,000 feet, 2,000 greater than that of the Springs, she feels comfortable. I certainly should not advise any one to go to Colorado for the cure of heart trouble, but when one is compelled to go there, the fact of his having a little roughness at one of the cardiac orifices will not be of itself a positive contraindication to his going. Cases of cardiac degeneration and enervation are the ones that suffer in Colorado, and in these the altitude may prove fatal. So long, then, as a case of valvular lesion of the heart gives rise to no discomfort, the compensatory hypertrophy being sufficient to compensate for the leakage or obstruction, there will be no difficulty, probably, in living at a moderately high altitude. But so soon as the dilatation is greater than the hypertrophy, and the heart muscle begins to weaken, will a valvular lesion be a great obstacle to living in Colorado. Persons affected with fatty degeneration of the heart should avoid high altitudes. Irritable hearts, due to a highly sensitive nervous system, bear exercise very poorly there. Irritable hearts, dependent upon weakness which is removable, do well.

It may be desirable to say a few words in regard to how invalids are affected on first going to Colorado. From what I have learned through the experience of other physicians and from my own observations, I do not believe that persons who are not extremely weak experience any unpleasant sensations. Invalids who go there and exercise too much soon after their arrival, as their feelings often lead them to do, soon begin to feel tired, and, perhaps, short of breath. Should a consumptive patient, on reaching Colorado, be attacked with spells of shortness of breath, without having exercised, it would be prudent, nay, urgent, for him to get away as soon as possible. Physicians, on sending their patients to Colorado, or any other high altitude, should impress upon them the necessity of living very quietly. I am not exaggerating, when I state that many cases are made hopeless, annually, by too great and too violent exercise. Horseback riding is for the select few only. Long walks and mountain climbing should not be indulged in for the first year, nor afterward without the advice and consent of a good physician. It is not infrequently the case that one meets with persons who are quite weak with pulmonary trouble, and who have been sent to Colorado, and told by their physicians to exercise all that they possibly could, and to do considerable horseback riding. Usually, such cases as follow this advice break down rapidly, either from spreading of lung trouble, or from the occurrence of hæmoptysis. Cases, as a rule, will not find an immediate amelioration of their symptoms on going to Colorado, but, on the contrary, cough and expectoration are frequently increased the first few weeks or months. When I went to Colorado I was firmly impressed with the idea that if I ascended the altitude rapidly, I should probably bring on a pulmonary hemorrhage. I spent about a week traveling from town to

town in Kansas, until I had reached an altitude of about 2,500 feet, when I determined to go to Colorado Springs at once. When I arrived there, I went immediately to bed, and was unable to tell, from my sensations, pulse, temperature, or respirations, that I was so far above sea-level. I learned from the physicians there that a hemorrhage is the exception in persons just reaching Colorado, especially if they keep quiet. I now believe that if the proper precaution is taken, there is no necessity for invalids to ascend the mountains gradually. There certainly would have to be an urgent need to induce me to attempt it again. The great drawback is that there are but few places after beginning the ascent of the Rocky Mountains, where you can be tolerably comfortable before reaching Denver or Colorado Springs. The best time of the year for an invalid to go to Colorado is September. The rainy season is about over, and that portion of the year which is so delightful is just beginning. Patients improve most during the fall and winter months. If they do not lose some during the spring months they are fortunate. Those that are cured by Colorado climate are few in comparison with the many that are benefit and enabled to live comfortably for many years. A small number are able to return East and live, but those who thus venture to do so, and break down the second time, receive much less benefit on again going to Colorado. It should be a rule, from which there ought to be as few exceptions as possible, that when a consumptive patient finds a climate that agrees with him, he should there make his home for the remainder of his life.

In conclusion, let me say something of the advantages and disadvanges of Colorado Springs. It has nearly six thousand inhabitants, numerous churches and schools, good hotels, and a number of first-class boarding houses. There are two parks, and the streets and avenues are wide and shady. The water which supplies the city is the melted snow from the Pike's Peak region, and is as nearly pure as possible, and delightfully cool. It is conveyed several miles through an iron pipe which taps the stream in the mountains above the point of possible contamination from human excrement. A large proportion of the inhabitants are intelligent professional and business men, who have been unable to live East. It is very doubtful whether one could find another place the size of it, in this country, where so much intelligence, ease and comfort exist. A great many there live oft the income of capital invested in other sections of the country. It is in many respects like a watering place, and in consequence, is far from being a brisk, lively, business town. It is possible to get nearly all the comforts there that can be obtained in a large city. The disadvantages are very great for those poor invalids who go there hoping to earn their expenses. It costs considerable to live there and fare as well as consumptive invalids should. Table board at the best boarding houses is eight dollars per week. Board and room vary from ten to fifteen dollars per week. It is very difficult for many to get anything to do to aid them in meeting their expenses. These facts should be known by consumptive persons in moderate or needy circumstances, before they make the journey of nearly two thousand miles to regain their health in Colorado Springs.

I have endeavored to make my remarks as practical as possible. I trust that I have succeeded without trying your patience.

ELECTROLYSIS IN URETHRAL STRICTURE.

BY C. A. BRYCE, M. D.,

Of Richmond, Va.

I notice in the MEDICAL AND SURGICAL REPORTER of Philadelphia for September 18 the following *resumé* of Dr. F. O. March's observations in the management of stricture by electrolysis:

RESUMÉ.

1. No appreciable amount of heat is developed in any metallic electrode imbedded in the living tissue. Even if such were the case the cautery could be no more destructive or painful than the molecular rending of the part by electrolytic action.

The choice of metal for needles or electrodes, or the selection of a special galvanic battery, is a matter of indifference, as far as the heat produced in the tissues is concerned.

2. The use of electrolysis for division of urethral stricture is unsuitable, being excessively painful and ineffectual. The passage of deep stricture with a mild current must be due to some other influence—perhaps the continuous pressure of the instrument upon the face of the stricture.

I am sorry that Dr. Marsh's article did not appear in full in the widely-read REPORTER, for then any comments from the advocates of electrolysis would have been uncalled for. As it is, one might infer from the emphatic manner in which his conclusions are stated, that they were reached after close observation and practical demonstrations.

I therefore beg leave to call the attention of your readers to a point or two not appearing in the "resumé."

In Dr. Marsh's report, appearing in the *Lancet-Clinic*, he states that his experience in the treatment of stricture by electrolysis is based upon a trial in *two cases!* We hold that under the most favorable circumstances this is not a *fair trial* of any system. But let us see if these *two cases* were treated in accordance with the recognized principles upon which success depends?

1. The battery used was larger than necessary, and had a tendency to do more harm than good, it being constructed of plates two by four inches in size.

2. His electrodes were peculiarly unfitted for the purpose, one being a wire ring, the other a bistoury!!

Experience has proved that these are not the most suitable electrodes for obtaining successful results. The acorn tip or solid bulb, filling the urethra well and presenting a smooth uniform surface well applied to the tissues to be absorbed, has been productive of the most good.

If Dr. Marsh was seeking to introduce innovations in practice or instruments, he should not lay his failures to approved and successful methods which he did not choose to adopt.

But apart from what we have written above, we now briefly notice the "resumé."

Conclusion No. 1 states that "the cautery could be no more painful or destructive than the molecular rending of the part by electrolytic action."

This we emphatically deny, and can produce hundreds of patients who will bear testimony that an electrolytic application produces *no pain whatever*, and yet does effect perceptible organic changes in the tissues.

Conclusion No. 2 is that "the selection of a special galvanic battery is a matter of indifference as far as the heat produced in the tissues is concerned."

We will not trespass upon your valuable space to explain that the doctor is likewise in error here, also. He must be told that "the selection of a battery" is a very important matter, for a battery with large elements will give a great *quantity current*, and may lack the essentials of *tension*. I would refer him to *Hayne's Elementary Principles of Electro-Therapeutics*, edition —, pp. 98 and 99, or any other standard work on electricity.

Conclusion No. 3 is that "the passage of deep strictures with a mild current must be due to some other influence—perhaps the continuous pressure of the instrument upon the face of the stricture."

We will answer Dr. Marsh's "perhaps" by suggesting an experiment which he or any one may try, and have an optical demonstration of the effects of electrolysis upon tissue. Take a piece of fresh beef, keep it at a temperature of 98° F., place two metallic rods (copper preferable) on the beef; to one connect the negative cord of a galvanic battery of from six to twelve cells, and complete the circuit by sticking into the beef a metallic pin connected with the positive pole of the battery. Now the *weight* of neither of these rods will cause them to sink into or cut down in the beef. But, put the battery in action and await results for fifteen to thirty minutes, and see which has begun to sink down and decompose the tissue. Furthermore, the action of the current, if a proper battery and proper strength has been used, will not be that of a cautery, for the beef in contact with the negative pole will appear as fresh and red as if it had been scooped out with a knife.

THERMO-CAUTERY IN THE TREATMENT OF HERPES.*

BY B. M. RICKETTS, M. D.,

Late House Surgeon to the New York Skin and Cancer Hospital.

In a paper read before the Cincinnati Medical Society, October 12, on the above subject, the author, after a review of the subject in general, reported the following cases:

Case 1. German woman, æt. 61, married, and the mother of three children. Two weeks previous to her visit some inflammation appeared from the median line to the right temple, accompanied by a small itching pustular eruption and swelling, with severe neuralgic pains throughout the affected side. She had suffered pain in the anterior portion of the head for about three months, never having experienced headache before. The scab formed in thirty hours after the pustules expelled their contents, and fell off within thirty or forty hours more.

Case 2. Man, æt. 69; occupation, lawyer. Four years ago he suffered from malarial fever, previous to which he had an abscess upon the right shoulder followed by one upon the left. Ten days before consulting me he suffered from severe pain in the right side. Empl. belladonnæ had but little effect. After removing the plaster the cuticle exfoliated, leaving an irregularly defined patch about five by ten inches, interspersed with pigmented papules. Upon the same side an-

* Abstract of paper.

terioriorly appeared a similar patch about five by twelve inches with an elongated papular patch extending down the flexor surface following the course of the ulnar nerve, the surface presenting a crusted appearance. There was slight itching and some burning attended by emaciation and loss of appetite.

As the cause of the herpes zoster seemed to be located in the spinal ganglia of the vertebra within the bounds of the eruption, why not direct our remedial course with reference to it? The ganglia are found firmly adherent to the parietes of the intervertebral canals. The neighboring connective tissue exhibits an inflammatory redness, and the ganglia as a whole are increased in volume. It was upon this theory that the thermo-cautery was applied. This was not done, however, until all other measures, both local and constitutional, had been resorted to. The skin was barely touched with the knives at white heat, done by a circular motion of the hand, the application being limited to the distribution of the affected nerve. This, however, was not done in the beginning of the first case, the patient having been placed upon large doses of the pills, arsenious acid gr. j. et piper nigrum gr. iv. made into twenty pills. This treatment was continued for one week without any appreciable benefit other than that which would naturally have followed. The pain continued, and the sleep was restless. It was controlled by the daily applications of the thermo-cautery.

In the second case its use two or three times daily was followed by the most satisfactory results. The burning and neuralgic pain was relieved. Sleep and appetite were restored. The course of the vesicles was shortened in being dried without laceration of the cuticle. When the pain is severe it may become necessary to apply the cautery every three or four hours. Lanolin or vaseline is perhaps the best preparation for keeping the parts softened over which the cautery has been passed. Starch should be used freely, with a broad soft flannel bandage. This plan of treatment has been but recently introduced, but it seems to offer better results than any other. I am not prepared to give the modus operandi. It may be that the destruction of the vesicles relieves the pain by removing the pressure which is produced by the exudation of serum. It may be due entirely to the local anæsthesia of the peripheral nerves produced by the cautery. Admitting that the lesion is in or about the ganglia, why not attribute our good results in this and many other cases treated by the cautery to some exciting influence upon them? In either case we have a remedy for herpes in any form that is worthy of careful consideration.

Discussion on Defective Vision and Headache.

Dr. W. Franklin Coleman said that in an examination of the eyes of pupils in Boston, in eighty-nine cases of defective vision fifty-nine were traceable to over-study. Out of this number twenty-five to fifty per cent. of the cases of headache which occurred were relieved by supplying suitable glasses. Another class of cases in which headache occurs is when there is weakness of the recti muscles. By supplying proper prismatic glasses this weakness may be overcome, and the headache disappears. Other factors in producing headache are improper light and too low desks, thus causing the pupil to strain the eyes. So far as artificial light to read by is concerned, the incandescent electric light is probably the best, as it most nearly resembles sunlight, and is free from heat, dust, and flickering.

Dr. F. C. Hotz said he believed the authors of such papers as this often exaggerate the importance of their observations. The result is, patients are often instructed to go to oculists, but do not do so on account of the expense, or for some other reason, and the patient therefore receives no treatment. But he has been surprised to see how few cases of defective vision come to him complaining of headache. He has not found it a prominent symptom. In looking over his record of cases he finds a great many cases of astigmatism, hypermetropia, and ametropia, in which the symptoms complained of are difficulty of vision, but not headache. Children often complain of not being able to see the figures on the blackboard, and consult the oculist for that trouble directly. But if a large number of cases of the eyes of children are examined, it will be found that in youth a normal eye is often farsighted, and yet such persons are able to do the work required. However, in cases of defective vision, accompanied by headache, the defect of vision should be corrected.

Dr. J. E. Colburn related his personal experience with astigmatism, stating that not only had he headaches, but he could not study well, and these difficulties disappeared with the using of proper glasses.

Note on "Cacur" (Cucumis Myriocarpus?), a Kaffir Emetic.

Dr. G. Armstrong Atkinson thus writes in the *Edinburgh Medical Journal* for July:

The extensive use of emetics in the treatment of disease by the Kaffirs of South Africa is well known to all dwellers with or travelers among these races. One of them most frequently employed emetics is a green, or yellowish-green, fruit known as cacur, cacuo, or small bitter apple. A small quantity of this, with some of the leaves and stalks of the plant, was recently given to me by Mr. J. A. B. Bayley, with the statement that the Kaffirs heat the fruit, squirt out the contents into their mouths, and swallow the material thus expelled. In a quarter of an hour, or thereabouts, emesis occurs. Two of the pepoes are so administered in the case of an adult, one in the case of a child. The plant grows largely in gardens as a weed, especially where melons and pumpkins are cultivated. The fruit is caducous, and, as I have mentioned above, is used by the natives when green or yellowish-green. When ripe it is quite yellow. It never spontaneously ruptures as ecballium fruit does. The plant was obviously one of the *Cucur-bitaceæ*, and Professor Oliver, of Kew, pronounced the pepo to be almost certainly the fruit of *Cucumis myriocarpus* (Naudin)—a green annual growing, according to Harvey and Sonder (*Flora Capensis*, ii., 495), on Table Mountain, near Genadenthal (Genadendal), at Buffelfontein, in the districts of Uitenhage and Albany. Mr. Bayley states that the plant from which the specimen he gave me was obtained grows not only where Harvey and Sonder mention, but throughout Cape Colony and the Free States generally. This identical specimen came from the midland province. The plant produces fruit very abundantly—subglobose pepoes, about the size of a large gooseberry, green when unripe, yellow when mature, and beset somewhat sparingly with short soft prickles. Each pepo weighs from 60 to 100 grains, and on section presents three parietal placentæ, with numerous seeds embedded in a soft viscid pulp, which becomes much more fluid when warmed—possibly the object of the heating practiced by the Kaffirs. The pulp has a faint cucumber-like odor, and is decidedly, but not intensely bitter. The rind is soft, and can only be peeled off with considerable difficulty; it, too, is somewhat bitter, but much less so than the pulp. The testa of the seeds, which are exalbuminous, have a feebly bitter taste; the seed otherwise is tasteless. The plant, apart from the pepoes, seems to me inactive.

To test its action, I took, on an empty stomach, 20 grains of the fresh pulp, and in about half an hour felt somewhat nauseated, but was not sick. Four or five hours afterwards I had some griping pains, and two or three hours after this was slightly purged. To a large fasting dog I administered, bruised with water, a pepo weighing 69 grains. No sickness was produced, and the dog seemed generally unaffected. In about eight or nine hours very watery diarrhœa occurred, which lasted for well on to twenty-four hours, the evacuations being bilious looking and containing much mucus. Some days later two pepoes, weighing together 118 grains, were administered in a similar manner, and in twenty minutes very free emesis occurred, the dog vomiting several times, the last vomit containing a little blood. Considerable salivation was also produced at the same time. After the vomiting ceased the animal rapidly returned to its normal condition, and no purgation followed.

From these brief notes it will be seen that the action of the drug is that of an emetic and of a cholagogue purgative; purgative in non-emetic doses, and in doses sufficient to produce emesis causing purgation, if sufficient of the active principle has been retained. Its emetic action is probably local.

As to the chemistry of the plant—I had, unfortunately, not sufficient material to make a satisfactory examination, but so far as I went I could find no trace of any alkaloid, the activity seeming to depend upon a bitter neutral principle, readily soluble in water, or in 80 per cent. alcohol. Professor Dickson has promised to grow the herb in the Botanic Garden, and Mr. Bayley hopes to provide me with a further supply of the fruit next year, so that I may then finish the investigation.

The Alternatives to Craniotomy.

Dr. Robert Barnes thus concludes an article in the *Brit. Med. Jour.*, October 2:

In conclusion, let me submit the following summary of the arguments set forth:

1. The legitimate aspiration and tendency of science is to eliminate craniotomy on the living and viable child from obstetric practice.

2. The advance of hygienic rule, the improvements in the forceps, in turning, in the induction of labor, and in obstetrics generally, have materially curtailed the field within which craniotomy can be justifiable.

3. In the most extreme degrees of pelvic distortion, where delivery *per vias naturales* can only be effected with doubtful success to the mother, Porro's operation is the legitimate alternative for craniotomy, it being understood that the opportunity of inducing abortion has gone by.

4. In less advanced degrees of pelvic contraction, but still incompatible with the delivery of a living child *per vias naturales*, the opportunity of inducing abortion having gone by, but in which craniotomy would effect delivery with strong presumption of safety to the mother, the Cæsarian section may be a proper alternative for craniotomy. This is the most debatable point.

5. In the minor degrees of contraction, say from three inches to three and a half or three and three-quarters inches, the opportunity of inducing labor having gone by, the far greater safety to the mother obtained by craniotomy, and the prospect of living children in future pregnancies by inducing labor, make craniotomy the proper course to adopt.

6. In other emergencies than deformity, as in obstructed labor from ovarian tumors, the alternative to craniotomy is to remove the tumor.

7. In cases of immovable tumors, Porro's operation is the proper alternative.

8. In rupture of the uterus, the child being delivered or not, Porro's operation is the proper alternative. There the interests of mother and child coincide.

9. In cases of disease or tumors of the uterus obstructing delivery, Porro's operation is the proper alternative.

10. In atresia of the cervix or vagina, Cæsarian section or craniotomy may be necessary; but incisions and gradual dilatation will more frequently be the proper alternatives.

11. When obstruction is due to hydrocephalus or dropsy in the child, embryotomy or tapping is indicated. When the child is dead, embryotomy is indicated, and decollation when the child is impacted, and turning is hazardous.

12. In convulsions and hemorrhages, the proper alternatives for craniotomy are found in the more scientific methods of conducting labor under these complications.

Lastly, the dream of Tyler Smith, the abolition of craniotomy, will be fully realized only when hygiene shall have triumphed over disease and deformity.

Hysterical Apoplexy.

Hysterical apoplexy is a complaint which has hitherto apparently been overlooked. Nevertheless, cases are by no means of rare occurrence. At a recent meeting of the Société Médicale des Hôpitaux, M. Debove communicated the following facts. On July 10th, a healthy man, aged 31, suddenly became insensible as he was leaving the dinner table; he remained in a comatose condition for twelve hours. On recovery, he presented motor paralysis of the left side; there was an absence of convulsions. The following morning, when he appeared at the hospital, there was motor paralysis on the left side, accompanied by hemi-anæsthesia. All the symptoms of the case established the diagnosis of ordinary apoplexy. M. Debove believed it to be hysterical. The patient was certainly strong and robust, and not of hysterical aspect. Nevertheless, on the left side the skin, mucous membranes, ear, and muscles, were insensible. The pupil was contracted; the patient was unable to detect violet, and had monocular polyopia. On applying a magnet, anæsthesia shifted from the left side to the right. On repeating the experiment, the left side became anæsthetized, and the right side presented its normal sensibility. When there was absence of organic lesion, motor paralysis was generally coëxistent with sensor paralysis of the region attacked. Professor Charcot admitted two varieties of anæsthesia—one hysterical, the other organic; the latter was rare. M. Debove's view was supported by a paper by M. Vulpian, which had appeared in a medical journal. The patient referred to in it presented hemi-anæsthesia, preceded by sudden loss of consciousness; these and other symptoms had led M. Vulpian to localize the cerebral lesion. At the necropsy, the two cerebral hemispheres were completely normal. M. Debove, in consideration of certain phenomena exhibited by the patient, affirmed that the case was nervous apoplexy. Notwithstanding the ætiological objection to the word hysteria, the disease might be called hysterical apoplexy, as it was a term under which was included a certain class of symptoms similar in kind. Hysterical apoplexy with anæsthesia was not astonishing. M. Debove reminded the meeting that, quite recently, in some cases of anæsthesia from

alcoholic intoxication, or saturnine or mercurial poisoning, the anæsthetic condition was connected with hysteria, and the anæsthesia was rather symptomatic than toxic.

Forcible Avulsion of a Finger.

M. Auché communicates to a Bordeaux medical society an account of a case of the rare accident of the complete avulsion of a finger. The patient was a carpenter, who, while engaged in lowering a heavy piece of timber by means of pulleys, got his finger caught between the rope and the block. By means of a sudden and violent effort he disengaged his hand, but left his third finger attached to the pulley. He felt but little pain, and there was no hemorrhage. When seen by the writer some hours afterwards the wound was found to be tolerably regular, the skin-flap representing pretty closely the ordinary oval or "battledore-shaped" incision employed in amputating the fingers. From the centre of the wound the proximal fragment of the first phalanx projected. Disarticulation was then performed, and the wound, the edges of which could not be brought together, was left open and dressed with iodoform. The finger was afterwards examined. The skin was normal on the two distal phalanges, but excoriated in several places on the first phalanx, showing that this was where the finger had been caught. The external digital artery and all the nerves had been divided at the level of the wound, the internal artery having been divided higher up and its end hanging out nearly an inch beyond the torn surface of the finger. The phalanx was fractured at the junction of the distal and the middle thirds, transversely but irregularly. The tendons were all left attached to the finger, those of the two flexors and extensors having been torn at their junctions with the muscular tissue, and hanging out for several inches from the torn surface of the finger. The writer states that forty-two cases of avulsion of fingers have been previously collected by M. Polaillon. In none of them, however, was the severance complete. M. Farabœuf has demonstrated that a force of 150 kilogrammes (about three cwt.) is required to effect separation subsequently to fracture of the bone, and even then several sharp wrenches are needed, during which, of course, the traction is very much greater than 150 kilogrammes. In this case the pressure of the rope on the finger against the groove of the pulley seems to have fractured the bone, and the sudden wrench given by the patient must have sufficed to tear the soft structures across.

Case of Strangulated Hernia Treated by Puncture.

Dr. James Brydon thus writes in the *Brit. Med. Jour.*:

S. M., aged 63, a thin, flabby, white-faced, average-sized man, had always enjoyed tolerably good health, with the exception of a hernia, which had troubled him for several years. Latterly it had been coming down more frequently, increasing in size, and becoming more difficult to reduce.

On August 7th, he was seized with a sharp attack of diarrhœa. Next morning, about 8 o'clock, while straining at stool, the hernia suddenly appeared in the left scrotum. All the means of reduction, which formerly had been successful, were tried, but failed. I saw him about 11 o'clock. The tumor was red and glistening, and reached halfway down to the knee. Symptoms of strangulation were well marked. The ordinary manipulation was used, but to no purpose; indeed, it was not long continued, as it gave rise to intense pain. Morphine was injected below the skin, enemata were given, and bags of ice applied. After two hours, the symptoms continuing unabated, taxis, under choloform, was again tried, but with no better result. As a large part of the tumor was tympanitic, evidently consisting of intestine distended with flatus, it occurred to me that, were this removed, reduction would be facilitated. I accordingly introduced a small trocar and cannula, and freed a large quantity of flatus. The hernia was reduced to a third of its original size, and its contents were without the slightest difficulty returned into the abdominal cavity. The patient shortly fell asleep, and slept for several hours. Next day he was comparatively well, was kept still, and fed on milk-diet. The bowels opened naturally that night; and on the third day he was out of bed, and going about the house. His recovery has been uninterrupted.

Whether this method of treatment has been used before or not, I do not know; but at any rate, in this case it was eminently successful.

Black Tongue.

Dr. J. R. Stocker thus writes in a foreign exchange:

Cases of black tongue being of rare occurrence, it may be as well to record them, and I therefore forward a short account of one

that has lately fallen under my notice, which closely agrees with the very able and accurate description given by Mr. Butlin, in his work on *Diseases of the Tongue.*

It occurred in the person of a friend, who is a nautical officer, aged 47, a widower with one child. His general health was good, but when first he noticed the condition, he had been suffering for some two or three weeks from a "lawn-tennis" strain (and bruise) of the calf of the leg. On June 16th or 17th last, he accidentally discovered on the dorsum of the tongue, and centrally situated, a large, dark patch, the size of half-a-crown; his attention being probably attracted thereto by abnormal sensation (metallic taste). The size of the patch gradually increased. He showed it to several medical men, only one of whom, he says, a ship-surgeon, seemed to take any practical interest in it; and he suggested the use of sulphurous acid as a wash. His own medical attendant, whom he saw incidentally the same evening, recommended him to use boracic acid. He tried first one and then the other, and says the latter appeared to be the most effectual, though he is somewhat doubtful as to the efficacy of either; he also used a whalebone scraper of a morning, and found that by this means, and by sponging it with the boracic acid, he could separate small shreds.

The color toned down from black to brown, from the centre to the sides, and about the first week in August (that is, in about two months) it gradually disappeared. The expression used by Raynaud (op. cit). of its resemblance to "a field of corn laid down by wind and rain," quite took his fancy. The tongue is still coated (September 16th), but the color is gone.

Since the loss of his wife, about a year ago, this gentleman has been much dispirited, and has lately had recourse to chloroform to obtain sleep.

Preliminary Notes on the Study of Malarial Blood.

Dr. William T. Councilman, of Baltimore, thus writes in the *Maryland Med. Jour.:*

Owing to the great number of malarial cases which have been received at Bay View during the last month, an unusually good opportunity has been afforded for the study of the blood, having regard to the recent interesting discoveries which have been made in this territory of research. Examinations of the blood, both fresh and when dried, have been made. So far both the bodies of Laveran and those described by Marchiafava and Celli have been found, but in a different class of cases. One case especially seemed to be of great importance. A man was received into the hospital from one of the Eastern Shore counties, apparently suffering with malaria, temperature 105°. He was at once given ten grains of quinine, with the result of an abatement of fever. An examination of his blood showed a great number of hyaline crescentic-shaped bodies with a mass of pigment in the centre. The quinine was stopped and the man continuad to improve under placebo treatment. Daily examinations of the blood were made and the crescents constantly found. On three occasions motile pigmented bodies were found. In order to study the effect of quinine, forty grains were given in two days with apparently no results on the condition of the blood. The motile bodies found were similar to those described by Laveran, though somewhat smaller. In one case of comatose malarial fever, in which death took place one hour after admission into the hospital, the diagnosis was made by an examination of the blood immediately after death. In this case the non-motile hyaline bodies were found. Other forms than the plasmodia were found in five cases, all of them representing the severer forms of the disease, with the exception of the one case mentioned, and this was the only one in which the crescents were found. The plasmodia described by Marchiafava and Celli are constantly found during the chill, and in some cases in the interval. It is difficult to understand how all these various forms should represent different phases in the development of one and the same organism.

Morphomania in France.

M. le Prof. Ball, the celebrated alienist of St. Anne, dedicated a special article in the *Journal de Medecine* to Morphomania, which is, according to him, rapidly assuming great proportions in France, especially amongst the gentler sex. The symptoms are very characteristic, but often the patient tries to put the medical attendant off the scent, and then some difficulty in the diagnosis is experienced; but if a close observation is made, something unnatural in the conduct of the person will arouse suspicion. For instance, if he is in a meeting his face will become changed and downcast, and he takes no longer interest in what is passing around him; but if he gets an opportunity of absenting himself a few minutes he will return quite bright as before; for in that short

interval he has given himself an injection. However there are two sure signs which will betray the patient, no matter how he may try to conceal his habit, and those are to be found in the skin and the urine. The skin will be found to be covered with little dark spots situated in the centre of little indurations about the size of a large shot. It is needless to add that these indurations are the result of the little wound of the needle, but as these lesions are generally found on the inside of the thighs, the patient refuses to let them be seen, and in that case examination of the urine will prove of great service. A few drops of tincture of iron are put into the suspected liquid, and if morphia be presented a blue tinge will be produced. The prognosis of morphomania[s] is not as fatal as is generally supposed, but there is a danger from the fact that the dose has to be continually increased, and in the end the cachexia becomes so pronounced that the patient falls an easy prey to tuberculosis. As to the treatment, M. Ball recommends a *brusque* suppression of the drug, provided the patient can be well watched, but in private practice he thought that it would be found necessary to proceed gradually. Preparations of belladonna might be employed to calm the irritation, or cocaine, but this latter remedy might prove to be as bad as the evil it was given to cure.

Excision of a Cerebral Tumor.

We have the pleasure of recording that another case of excision of a cerebral tumor has terminated successfully. The patient was a man who had been absolutely hemiplegic for a month, and had passed into a semi-comatose condition; before these symptoms developed, he had endured terrible pain in the head, and had suffered from fits. On Thursday, September 23d, Mr. Victor Horsley, of London, trephined over the motor region of the right hemisphere, and, after enlarging the aperture made by the trephine, succeeded in removing a large tumor from the brain; the tumor weighed four and a half ounces, was three inches long, two and a half inches broad, and two inches deep. On the day after the operation the patient was perfectly rational, and even amusing in his conversation, and said that he was quite free from pain. On September 27th, the wound was entirely healed, and the man had recovered some power in his leg. This is the fourth case in which Mr. Horsley has operated successfully on the motor area of the cortex of the brain. His results constitute a real triumph for scientific surgery. Not only have the facts upon which the diagnosis of the seat of the lesion in these cases rests been discovered by experiments on lower animals, but the details of treatment have also been worked out in the course of these experiments. The complete success of the surgical method followed is demonstrated by the fact that, in two of the cases, the wound healed in four days; that, in a third, it had healed in a week; and that, in the case which was in this respect the least successful, the whole of the wound, with the exception of one-sixth, healed by first intention. A more complete proof of the validity of well directed experiments on animals it would be difficult to imagine; and it is no wonder that the professional agitators, who are beginning to find their supposed grounds of objection one by one swept away, pursue Mr. Horsley with a bitterness which increases as it becomes less reasonable.

Phimosis with Exaggerated Symptoms.

Dr. T. M. Holmes thus writes in the *Atlanta M. and S. Journal:*

Some months ago I was called to see a mulatto boy about five years of age, who had been suffering for several days from profuse diarrhœal discharges and frequent micturition. He was very much reduced in flesh; his features were pinched, and his skin was dry and harsh. His eyes were of a smoky hue, and he was almost blind. He also had a papular eruption from the crown of his head to the soles of his feet, with a serous discharge not unlike that of eczema. There was more or less pain in the region of the bladder all the while, which was greatly intensified by the accumulation of a small amount of urine in this viscus. When this occurred he would run the floor, compressing his abdomen with his hands, and cry in such a manner as to enlist the sympathy of all lookers-on. He had been losing his vision for several weeks and growing very nervous.

What could be the exciting cause of this amaurosis, this diseased skin and nervous phenomena? I sought to discover it, which resulted in finding an almost complete phimosis and partially closed meatus.

The diarrhœa was successfully treated, but with no abatement of the other symptoms. It was evident to my mind that the patient was suffering from a severe nervous irritability, the result of the phimosis, and a slow uræmic poisoning, the solid constituents of the urine having been re-absorbed from the retained urine in the bladder. I first sought

to relieve the patient by dilatation, which failed to give the necessary relief on account of the condition of the meatus. I therefore performed circumcision, with the assistance of Mr. George Glover. The result was a complete relief and a disappearance of all the above symptoms. The boy is now in fine health.

A Disease which Followed Vaccinations at Rugen in the Summer of 1885.

Eichstedt (*Berliner Klin. Wochensch.*), reports on a contagious skin affection which was caused by vaccination at Rügen in 1885. The vaccinator had obtained from Stettin lymph from a healthy child. To this lymph, thymol and glycerine were added, and with this diluted lymph the first seventy-nine vaccinations were made, out of which seventy-six persons became infected with this disease. From these, further infections took place until a total of 320 persons were affected in the same way. Between the eleventh and fourteenth days after successful vaccination, small and rapidly enlarging vesicles formed in the neighborhood of the vaccination-punctures. The contents quickly formed crusts, which, in from two to four weeks, left a deep red non-desquamating spot, which disappeared in a few weeks. There was only slight fever, and little itching or pain. Soon after the appearance of the vesicles a further eruption took place on the back, hands, face, neck and ears of the patients. On the trunk, they occurred particularly on the loins and hips, and on the extensor surface of the legs and arms, and on the back of the feet. Very few came on the flexor surfaces. There were slight glandular swellings. The whole course of the eruption extended over from four to six weeks. When there were relapses, the disease lasted several months without injuring the constitution. The disease was undoubtedly infectious, the contagium being a fixed body, as it only spread by contact. Children were more exposed to infection than grown-up people, in whom also the symptoms were slighter. The author considers the disease to have been impetigo contagiosa. He found no fungus, and considers that the contagium must have been present in the glycerine which was added to the lymph.

Granuloma Fungoides.

An account of a case of the rare affection, Granuloma fungoides, has been published by Drs. Carl Hochsinger and Eduard Schiff of Vienna. Their paper also appeared in the *Vierteljahreschrift für Dermatologie*, No. 3, 1886, but the authors were not enabled to revise it, and they have therefore felt bound to issue it in a separate form. It will be read with interest here in connection with the remarkable case described by Dr. Payne last session at the Pathological Society. The disease began in 1877 as a chronic eczema of the back, which gradually spread over the body. In 1883 the head was attacked, and soon became the seat of the characteristic ulcerating nodules. The patient, a female, died in November, 1885. The authors give a historical sketch of the affection, and describe its histology as a nodular formation of granulation tissue replacing the normal tissue of the cutis and the papillary body. A delicate reticulum supports the round cells, and in no part are any giant-cells detected. The transition to healthy skin is gradual. The new growth is not very vascular, and as it spreads it rapidly destroys the cutaneous capillaries. Described previously under such names as *lymphadenie cutanée*, "sarcomatosis generalis," its alliance with specific inflammatory formations has been proved by the discovery of micro-organisms in the tissue; so that Rindfleisch gave it the name of Mycosis fungoides. Hochsinger and Schiff in the present case ascertained the presence of streptococci in the vessels, leading to the obliteration of the latter; and they instituted a series of culture-experiments, which are described in their paper, and which prove that the micro-organism is distinct from the pyogenic forms.

The Teutonic Complexion.

Professor Virchow has recently turned his attention to the color of the hair, eyes, and skin among the school children in Germany, and has prepared some interesting tables relating to the subject. The territorial division of the principal types corresponds accurately to the geographical boundaries of north, south, and middle Germany—over 43 per cent. of the pure blondes being found in the northern districts, over 32 per cent. in the middle, and over 24 per cent. in the southern ones. The river Main thus becomes an anthropological line of significance. In general, the further south one goes, the more brunettes one meets, South Bavaria mustering but 14 per cent. blondes. Among the 75,376 Hebrew children, the mixed type also predominates; the pure brunettes outnumbering the pure blondes, however, three-fold; whereas the relation of the blondes to the brunettes among the Christians is 31.8 to 14,

that among the Jewish children is as 11.29 to 42. The grey-eyed and dark-haired predominate in the mixed type, The racial significance of complexion is a matter of high interest to all who love science; but there remain questions in relation to the color of the hair and skin which may prove to be of physiological or even pathological import. The tow-like hair, with its peculiar tawny yellow tint, often seen in the inhabitants of the northern Scottish islands, and in other parts of the United Kingdom where peasants walk bareheaded, is well known to tourists, and is clearly the result of the action of the air, sun, and damp. Amidst the sickly offspring of the inhabitants of large towns, extreme darkness of the hair and iris, with a clear rosy complexion, is frequently observed. It probably represents a pigmentation due to some special form of anæmia.

Varix of Labium: Rupture During Labor.

Dr. Ambrose Atkinson thus writes in an English exchange:

A little time ago I attended a Mrs. F., aged 39, in her eighth confinement. Labor commenced about eight o'clock in the evening, though she had been ailing for over twenty-four hours. On examination, a breech was made out. After a short time, it came well down into the pelvis, and, when it was near the outlet, the right labium began to swell. Delivery was easily effected, and whilst the child was being separated, the patient was seized with another very strong pain. On examination, made with difficulty, a second bag of membranes could be felt. The tumor, however, steadily increased to an alarming size. Another pain coming on, the tumor suddenly burst on its inner side, deluging the bed. Not caring to take the whole responsibility of the case, I sent for Mr. Holmes, of Burmantofts, requesting him to bring his forceps. In the meantime, as hemorrhage was freely going on, I made a firm pad of a napkin, and held it to the parts, so as to effectually stop the bleeding. On Mr. Holmes's arrival, he put the short forceps on the second head. The child was suddenly expelled, the injured part, at the same time, being firmly compressed. The placenta was easily disposed of. On examing the damage, it was found that the inner side of the labium was so torn that four fingers could be passed into the opening, which led to a cavity sufficiently large to hold the whole hand. The bleeding had now abated; the cavity was, therefore, filled with strips of lint, and iodoform was well dusted on. Pressure being applied by means of a firm spica bandage, the patient was left for the night, opium being given. The following morning the plugs were removed; very little bleeding occurred. The vagina was syringed out with a solution of perchloride of mercury (1 in 3,000); an iodoform suppository was placed well up into the vagina, and the wound was dusted with iodoform; this was done twice daily for a week. The patient made a very good recovery. A piece of vein, about three-fourths of an inch long, which lay across the wound, sloughed off about the fifth day, a little bleeding taking place. On questioning the patient about the veins, she told me, after all was over, that she had had a lump there for some time, which became larger towards night, but she did not think it worth while to tell me. Supposing I had known about it before delivery, could anything have been done to prevent rupture?

Phthisis in Denmark.

Dr. Lehmann has contributed this year some important statistics on the subject of phthisis in Denmark. He examined the death-rates in the Danish towns from 1876 to 1883. He divides the deaths from phthisis into three classes: First, those during the development age to twenty; second, those during the vigorous years, from twenty to fifty-five; third, those during the later years, from fifty-five to old age. He shows that the mortality from phthisis is, in the smaller towns, one-fifth less than in Copenhagen, which contains a population of 300,000; in the capital, too, mortality amongst men is greater than that amongst women; whilst, in the smaller towns, the mortality of the sexes is almost equal. Phthisis has a slower course also in smaller towns than in Copenhagen. Up to the age of twenty, more women than men die of it; after that, more men than women. With regard to the geographical distribution of phthisis, the mortality in Jutland is 2.6 per 1,000 living. It is about the same in Seeland, but only 1.55 in the Southern Islands. The greater immunity of these islands was demonstrated by the recruiting returns of 1875–1884, during which period 9.4, out of every thousand men taken from Jutland, were rejected on account of phthisis; whilst only 3.74 of those from the Southern Islands were declared unfit. The mortality from phthisis is greatest in those towns of Jutland which lie in the inland or coldest parts of the country, and rarest on the coast, which is warmer, and in towns situated in the neighborhood. With regard to the country districts, Dr. Lehmann has had to place his dependence on the

accounts of private medical men, hence the materials are not equal to those furnished by the hospitals. All accounts agree, however, in stating that phthisis is on the increase, as well as chlorosis, cardialgia, and scrophulosis. It appears, also, that tuberculosis of cattle is on the increase.

A Strange Case of Strangulated Hernia.

Dr. L. Ladmirault thus writes in the *New Orleans M. and S. Jour.*:

On the 15th of May, 1859, I was called to an African negro, aged about 66 or 67 years, suffering from a strangulated hernia of four days' duration. As he was in the habit of reducing the hernia himself, he had remained that long without asking for help. Stercoraceous vomiting, hiccough, the weakness of the pulse and coldness of the body, seemed to indicate approaching death. At the request of his master I began the operation, assisted by him and an intelligent neighbor who administered the chloroform. The hernia measured ten inches by five. After incising the tissues and opening the sac, a loop of the small intestines about fifteen inches in length was exposed, distended only by the accumulation of gases, of a dark color, nearly gangrenous. The inguinal ring, although very large, admitted with difficulty the probe-pointed bistoury. An incision was made directly upward at the internal portion of the ring, so that the finger could be introduced into the ring, but reduction was still impossible. Drawing the intestines further out, I discovered that back of the inguinal ring the bowel was twisted twice on itself as a sausage. By untwisting it and driving up the gases in the rest of the intestines, the hernia was so diminished in size that it was returned without difficulty. Reduction took place immediately. Cicatrization was rapid; and the patient was soon able to return to his work, wearing a truss.

Depressing Effects of Antipyrin.

Dr. Edwin Fairland thus writes in the *Brit. Med. Jour.*:

This drug has recently been administered in several cases of high temperature occurring in the station hospital at Peshawur. Some of these cases were suffering from enteric fever, others from remittent fever. The temperatures ranged as high as 105°. The administration of the antipyrin usually, not invariably, was followed by a steady decline in temperature to the normal point; but the intermission rarely lasted more than from twelve to twenty-four hours. The drug had no permanent influence in reducing temperature, or modifying the *materies morbi*. But in one case more serious results occurred. A dose of thirty grains of antipyrin was administered to a case of enteric fever, thirty-three days in hospital, and slowly recovering. All acute symptoms had subsided, but the evening temperature remained high—104°.

In about four hours after the medicine was taken, the temperature fell at once to 95°, and this was accompanied by the most alarming collapse, sighing respiration, cold extremities, clammy surface, and feeble pulse. In a few hours, under stimulants, these depressing symptoms disappeared; and at 6 a. m. the temperature was again at 104°. The drug was not tried again in this case; and my recent experience has led me to look with a little suspicion on so uncertain a remedy.

Urethan in Mental and Nervous Diseases.

Drs. Otto and Kœnig (*Centralblatt für Nerven Heilkunde*) have studied the action of urethan in a large number of insane patients of different sorts. In some forms of paralysis, four to eight grammes were given, but in a condition of strong excitement, the action was doubtful. They found it useful in doses of from two to four grammes for epileptic patients where there was a condition of no great depression; larger doses were not found advisable on account of the unpleasant effects on the stomach. Urethan did good service in excited conditions of idiotic children; in the paralysis of men, with slight excitement, small doses from three to four grammes were found to be useful; in severer cases, it was very untrustworthy even in doses of ten to twelve grammes. Kraepelin has given urethan as a hypnotic especially in mental diseases, and only in doses of one to three grammes (fifteen to forty-five grains). He never observed any unpleasant effects. Sleep occurred ten to fifteen minutes after swallowing the drug, and continued for several hours. He did not use it in cases of strong excitement. Kraepelin found that, in 60 per cent. of paralytic cases, urethan acted favorably. It was also serviceable in melancholia, and in cases of great mental anxiety; as much as 77 per cent, of these cases were benefited by it. Rothenbiller found that urethan in doses of two to four grammes gave several hours' sleep to patients with slight excitement. He also used subcutaneous injections of a quarter of a gramme (nearly four grains). One to three injections insured six to eight hours' sleep.

Prophylaxis of Phthisis.

At the recent meeting of the British Medical Association, Mr. G. W. Hambleton read a paper entitled "The Scientific Prevention of Consumption," based upon his views as to the etiology of the disease, which are embraced in the sentence, "Those conditions that reduce the breathing surface of the lungs below a certain point in proportion to the rest of the body." The conditions in question are, as may be expected, very numerous, comprising sedentary occupations, overcrowding, want of exercise, defective seats, clothing, etc., leading to habitual disease of the lungs or the undue compression of the chest. In fact, consumption is, on Mr. Hambleton's doctrine, invariably "acquired." Its prophylaxis, then, requires a free country life, well-ventilated rooms, suitable chairs, and clothing free from constriction, and not too heavy. The physical training, commenced in the nursery, should aim at the full development of the thorax, and all out-door occupations and amusements should be encouraged in youth to this end. Unless the breathing capacity, as shown by measurement, is up to the normal, the individual should not engage in any trade or occupation such as would compress the chest or injure the lungs by inhalation of dust; whilst those who have to follow such pursuits should by exercise of the lungs endeavor to counteract their evil effects. All of which advice, without being novel, is sound and forcible; whilst if it could be followed as widely as Dr. Hambleton would wish, it would doubtless do even more for the public health than reduce the mortality from consumption.

Yellow Fever: its Transmission by the Culex Mosquito.

Dr. Charles Finlay, of Havana, maintains, in an article which appears in the October issue of the *American Journal of the Medical Sciences*, that yellow fever is not spontaneously transmissible by infection through the air by contact, but that it may be artificially communicated by inoculation, and only becomes epidemic when such inoculations can be verified by some external natural agent, such as the mosquito.

The history and etiology of yellow fever exclude from our consideration as possible agents of transmission other blood-sucking insects, such as fleas, etc., the habits and geographical distribution of which in no wise agree with the course of that disease; whereas, a careful study of the habits and natural history of the mosquito shows a remarkable agreement with the circumstances that favor or impede the transmission of yellow fever. So far as Dr. Finlay's information goes, this disease appears incapable of propagation wherever tropical mosquitos do not or are not likely to exist, ceasing to be epidemic at the same limits of temperature and altitude which are incompatible with the functional activity of those insects; while, on the other hand, it spreads rapidly wherever they abound. From these considerations, taken in connection with his successful attempts in producing experimental yellow fever by means of the mosquito's sting, it is to be inferred that these insects are the habitual agents of its transmission. It cannot be denied, however, that other such agents may and probably do occasionally occur, but not being endowed with the same facilities for rapid and extensive operation, their influence becomes insignificant as compared with the action of the Cuban culex.

Removal of the Ovaries for Persistent Neuralgia.

At the Société de Chirurgie M. Terrillon related the case of a patient from whom he extracted both ovaries and both fallopian ligaments for persistent neuralgia two months ago, The woman has since been perfectly free from pain. M. Verneuil cited a similar case, but with only temporary relief. M. Reclus expressed himself delighted with the result of the case of his colleagues. M. Terrillon said that under similar circumstances he would not hesitate to follow his example. M. Lucas explained his treatment of peri-articular fractures, which consisted in massage, and the result obtained was very satisfactory, especially in cases of fracture of the fibula. Another member thought that massage was in certain cases difficult, and might be advantageously replaced by Esmarch's bandage. M. Trelat considered that massage did, by no means, answer all the requirements in the treatment of fractures. It was forgotten, perhaps, that a fracture meant, in most instances, separation of the bones, and the chief aim of the surgeon was to reunite them, massage, for instances in fracture of the rotula, might prevent atrophy of the muscles, but would not keep in position the fragments. M. Lucas, in replying, cited a characteristic case of fracture of the radius, which was treated exclusively by massage, and movements were restored to the arm in eight days.

Fatty Placenta Causing Abortive Hemorrhage—Treatment.

Dr. W. J. Strother thus writes in the *Virginia Med. Mo.:*

Mrs. H., aged thirty years, married seven years, has had six to seven miscarriages, generally happening from three to five months, beginning about the second month with hemorrhage, which returned every few days until fœtus was expelled. She had a miscarriage about fifteen months ago, at which I attended. Remembering a case (as reported in a medical journal), of miscarriage being due to fatty placenta, and that muriated tincture of iron and chlorate of potash had been used successfully in the succeeding pregnancy, I examined the placenta and found it almost a mass of fat. At the beginning of her next pregnancy I gave the following mixture almost daily until she was delivered of a healthy male child at full term, and she had only a slight show of hemorrhage, which was about the third month:

℞. Tr. ferri chl.,	ʒ iij.
Potass chlor.,	℥iij.
Glycerini,	ʒj.
Aquæ,	ʒv.

M. S.—Teaspoonful *ter die.*

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——A pamphlet of 52 pages entitled *Des Cataractes et de Leurs Operations*, by Dr. Galewzowski, appears from the office of the *Progres Medical*, Paris. Price 30 cents. It is a neat clinical exposition of the subject.

——A pamphlet of 55 pages, by Dr. Charles W. Dulles, reprinted from the *Transactions* of the College of Physicians of Philadelphia, describes the mechanism of fracture of the skull. A number of illustrations are appended to the text, and various cases are described. For sale by P. Blakiston, Son & Co., Philadelphia.

BOOK NOTICES.

The Science and Practice of Surgery. By Frederick James Gant, F. R. C. S., etc. Third edition, revised and much enlarged throughout, with 1090 illustrations. In two volumes. Pp. 1089 and 1183. Half Russia, marbled sides and edges. Price (by express prepaid), $12. London, 1886. For sale at Philadelphia by D. G. Brinton.

The previous editions of "Gant's Surgery" have met with a highly favorable reception in India, England, America, and, in short, wherever the English language is read. Encouraged by this, the author has given to the present edition a great deal of time and labor in order to make it representative of the most recent advances in surgical science, both in general departments and in those usually considered as specialties. In the latter, he has received the able assistance of some of the most distinguished specialists of the British metropolis. Thus, Dr. Morell Mackenzie contributes the chapter on Diseases of the Throat and Larynx; Dr. Robert Barnes that on Diseases of the Female Genital Organs; Mr. Henry Power that on Diseases of the Eye, etc.

Of the special branches discussed in this manner we may mention, besides the above, a very interesting chapter on "Bacteria in Surgery," and the value of antiseptics in operations, by that eminent authority on this branch, Mr. Watson Cheyne, of King's College Hospital; a discussion of the latest methods of Treating Cleft Palate, by Mr. William Rose; Dental Surgery, and Diseases and Injuries of the Jaws, largely written by Mr. Tomes; an excellent chapter on Diseases of the Skin; and a special feature of the work is the thorough presentation of diseases of the genito-urinary organs, specific and in relation to cystotomy, vesical tumors, and lithotomy. Abdominal operations for the cure of otherwise incurable diseases of the viscera, constitute two entirely new chapters in this edition, and this important subject for the first time receives the prominence it merits in a text-book of this science. Careful attention has been given to explaining the application of new and improved apparatus, and several new and important surgical operations are fully described both with regard to their design and performance.

The exhaustive character of the revision and editing of this new edition may be judged by the facts that over two hundred special engravings have been added, and about four hundred and fifty pages of reading matter. In its present form the work may be regarded as both the most recent, the most comprehensive, and the most authoritative presentation of the science and art of surgery in our language.

The present is the original English edition, on superior paper, admirably printed, substantially bound, and supplied with the most complete indexes.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

BE CAREFUL ABOUT YOUR DIAGNOSIS.

There is a case incubating in this state about which we will have more to say if it reaches maturity, that possesses very peculiar interest for physicians. It seems that a young lady sojourning at a summer resort was taken ill, and it was the opinion of the resident physician of the hotel and of the patient's brother, himself a reputable practicing physician of this city, that she had typhoid fever. They discovered what they considered to be sanitary defects about the premises, and they notified the State Board of Health, when an inspector was sent to the premises. Anticipating his coming, some of the defects were remedied, but in his report he makes it clear that when he visited the premises there were still several matters not as a wise sanitarian would ordain.

But the portion of his report with which we have especially to deal is the fact that, for some reason, he makes strenuous efforts to prove that the case was not one of typhoid fever. He never saw the patient, and based his doubt of the correctness of the diagnosis of two reputable physicians on the temperature record, which is universally conceded to be a very variable and uncertain factor in the diagnosis of this disease. Upon the strength of his doubting report, it is stated by another physician that the diagnosis of the original attending physicians was a mistake, and that the case was not typhoid. Now comes the important point. Because of the denial of the correctness of the diagnosis, the owners of this resort have threatened to bring suit against the two regular, reputable physicians in good standing, for the damages sustained on account of their verdict that a case of typhoid fever was contracted on their premises.

The importance of this case to the universal profession cannot be over-estimated. If such a suit were maintained, it would mean that a physician would never be safe in expressing his opinion that a patient was suffering from an infectious disease. Remember that one of the physicians who made the diagnosis was the resident physician of the hotel wherein the case occurred, so that there was every inducement to hush the matter up; but also remember that he was a reputable physician, and that his sense of duty was superior to his sense of self-interest. We call attention to this case because we think it well that the whole profession should be familiar with the danger that may at any time threaten any one of them, and also to say to those who contemplate this suit that they had better "look before

they leap," for in bringing a suit that will serve to establish a principle of such vital importance to the profession, they would find arrayed as defendants not only the two physicians whose diagnosis has been questioned, but every reputable one of the eighty thousand physicians of the United States. These two physicians would be entitled to and would receive the hearty support of their brethren throughout the length and breadth of the land. The principle is a vital one, and we will fight for it.

REPORT YOUR CASES.

The gradual additions to human knowledge that have been made year by year for centuries past stand now collated as the sum total of information of the people of the nineteenth century. That which was worthy, that which was calculated to redound to the benefit of the human race, has been preserved and put into permanent shape, accessible to all; that which was worthless has been forgotten. As with general, so with medical knowledge. It is the aggregation of individual experiences, sifted, sorted, reasoned upon, and elaborated, that make up the sum of our knowledge of to-day. No case is too trivial to be instructive to the thoughtful and observant physician. In every case such a man will find something to ponder upon, and having so pondered, he should give the benefit of his reflections to his brethren.

The experiences and reflections of the *practical* man should be recorded in the medical periodicals. Then comes along the literary man, who gathers about him this mass of valuable information, sorts the chaff from the wheat, arranges, brings all this knowledge into order, and the valuable textbook is the result.

The majority of men seem afraid of the pen. There is scarcely a physician who will not readily sit down and tell you of some interesting experience that he has had, and tell it well, so that he instructs you; but ask him to put what he has said into writing for publication, and he at once says either that is "*not much at writing*," or has no time, or puts it off for the *to-morrow* that never comes. It is almost inconceivable how much valuable material is thus annually consigned to oblivion. This is to be greatly regretted, and we desire to strongly urge upon all physicians to "write more." Never mind if you do not possess a "literary style," or if your pen does not glide over the paper with the facility of a Gross, a Bartholow, a Stillé, or a Flint; send in your contributions clad in good, honest *homespun*, and we will find a place for them—for it is just such plain, practical material that, in our judgment, tends to increase our knowledge of the healing art.

Notes and Comments.

The Treatment of Excessive Salivation During Pregnancy.

Owing to the ordinary insignificance of this ailment, few medical works contain a lengthened account of it. Dr. Y. Schramm, however, had the opportunity, in the autumn of 1885, of observing a very severe case, and he has published some notes of it in a Scandinavian journal. Numerous remedies were employed with very little effect, for at first he imagined the salivation to be due to chronic mercurialization; but, later, he discovered that the patient was pregnant, and that pregnancy was the cause of the condition. Neither the iodide of potassium, recommended by Le Maestre, nor Von Ebstein's atropine treatment, had any effect. Galvanizing the sympathetic also exercised only a very slight effect. Galvanizing the cervical sympathetic was resorted to with no perceptible result. Dr. Schramm then tried subcutaneous injections of pilocarpin (as recommended by Von Labbe and Daveyeux). After seven injections of pilocarpine chloride, 0.01 gramme per dose, there was a diminution of the daily quantity of saliva, as well as improvement in the general health of the patient. The excessive secretion, however, could not be entirely stopped. Bromide of potassium was tried, which acted quickly in the reduction of the flow; and Dr. Schramm prefers bromide of potassium to all other drugs, as it is harmless during pregnancy, and yet exercises a distinct effect on the salivary nerves, and on the origin of the facial nerve in the medulla oblongata, and also on the secretory filaments of the sympathetic. Professor Fleck made a chemical examination of the saliva, and found that ptyalin was absent.

Action of Tin on the Animal Organism.

The accidental poisoning by "tinned provisions," which has been attributed to the formation of stannous or stannic salts, has induced Dr. T. P. White to investigate the subject experimentally (*Pharmaceutical Journal*). The conclusions arrived at are: that tin has a direct irritant action on the intes-

tines, increasing peristaltic movements; that it causes weakness, as the result of some action on the spinal cord; that it irritates some of the nuclei about the floor of the fourth ventricle, said to be shown in convulsive tremors and disorder of respiration; that the heart is not directly affected; and, lastly, that experiments with the metal, when acted upon by muriatic, acetic, or "fruit" acids were decidedly unsuccessful. It is therefore considered that tin, though possessing toxic properties when introduced into the blood, is devoid of danger when taken internally in any form that could result from contact with fruit or vegetables. Dr. White regards the cases of accidental poisoning as due to the solder used in sealing the cans, or to impurities of arsenic, copper, and lead in the tin itself.

Spiræa Filipendula in Hydrophobia.

A Polish medical man, Dr. Fürst Ignatz Jagell, who says he has for five and twenty years interested himself in the treatment of hydrophobia, declares in a Russian journal that during that period he has treated 88 persons who had been bitten by rabid dogs or wolves, 26 of the patients having already commenced to exhibit the early symptoms of hydrophobia. Notwithstanding this, however, he did not lose a single case. They were all treated with the same remedy, viz., an infusion of the cortex spiræa filipendula (dropwort). It is needless to say that Dr. Jagell does not approve of Pasteur's proceedings; but how is it that we have not heard of his own remarkable success before? The plant he uses is not entirely unknown to pharmacy, the root and the leaves being sometimes employed, and believed to have astringent and diuretic effects.

Dislocation of the Testicle.

Dr. Smith reports in the *Indian Medical Gazette* for July, 1886, the case of a soldier who was struck with a rifle-butt in the scrotum. He complained of great pain, and examination showed absence of the left testicle from its normal position, and the presence of a small rounded tumor, very sensitive on pressure, in the groin about at the internal ring. Nothing was done for the man except to relieve him of heavy work. Some months later the soldier died of beri-beri, and on post-mortem examination the testicle was found lying within the abdominal cavity, where it had contracted some adhesions to the peritoneum. A slit was seen at the internal ring, through which the little finger could be passed into a pouch running toward the scrotum. The man stated, at the time of the receipt of the injury, that the two testicles had always been present in the scrotum up to the time of the accident.

A Suggested Alteration in the Compound Liquorice Powder.

Having found that the above preparation produced very severe griping in many instances where he had ordered it, the griping being particularly severe in some of his younger patients, Dr. Martin Oxley (*Lancet*), has ordered the following formula for some time past, in which anise fruit is substituted instead of the fennel, and one-fourth part of ginger is added. The altered formula runs thus—senna and liquorice-root, of each 2 parts; anise fruit and sulphur, of each 1 part; sugar, $5\frac{3}{4}$ parts; ginger, $\frac{1}{4}$ part. This altered preparation is quite as satisfactory in its laxative properties, is less liable to gripe, and is as pleasant to take as the officinal powder, and he would suggest its trial in cases where the powder as now prepared produces the disagreeable effects to which he has referred.

Faradization of the Uterus as a Hæmostatic Agent.

In the *Bullet. Général de Thérapeutique*, Ramos gives details of a case in which a slight but persistent hemorrhage followed abortion in a multipara. After a careful examination, the absence of placental remains or tumor was recognized. All available agents, such as ergot, perchloride of iron, and plugging, failed. The patient becoming steadily weaker, electricity was tried as a last resource. One pole of the battery was placed upon the abdomen over the symphysis, and the other placed directly on the cervix. The patient had pains, and in five minutes the bleeding ceased. Three days later, hemorrhage again commenced, but ceased after a prolonged application of the battery. Under tonic and hydro-therapeutic treatment the patient recovered completely.

Colombine.

M. Roux has observed the effect of pure colombine on fowls, the only animals which he has been able to get to take the medicine by way of the mouth. The symptoms produced by the ingestion of the poison were those that are associated with fatty degeneration of the liver and destruction of its working elements. Colombine irritates the intes-

tinal tube, causing increased secretion from the gastric, intestinal, and biliary surfaces. The occurrence of these serious symptoms makes it necessary that the administration of the drug to human beings should always be in the form of small doses. The daily dose to commence with should not exceed one centigramme of the alkaloid, and the powders of columba are to be preferred to the less certain alcoholic and ethereal liquid extracts.

Squills in Whooping-cough.

M. Nettier, of Nancy, has treated a number of cases of whooping-cough with simple oxymel scillæ, which he observes ought to be ascertained to be good, as specimens to be found in pharmacies are of very different qualities. He advises the entire abandonment of cough syrups, and gives the squill even when there is diarrhœa and a good deal of vomiting. In the case of children who do not expectorate, he even adds emetic drugs to the squill. He has seen cure result from this method of treatment in a few days, cases of failure being very rare. A colleague of M. Nettier, M. Remy, corroborates his statements, and says he has seen cases that have been going on for weeks yield to oxymel scillæ in a few days.

Cocaine in Uncontrollable Vomiting in Pregnancy.

Dr. F. Engelmann, in the *Centralblatt für Gynäkologie*, No. 25, 1886, records a case of extreme prostration and emaciation due to vomiting of pregnancy, in which cocaine seems to have acted as a charm. He says: "Ten drops of a 10 per cent. solution were taken thrice daily. After the first dose, which was taken in the evening, patient felt better, so that she tried a drink of water, which produced no inclination to vomit. After two days the solution was taken in smaller doses, and then stopped. Neither vomiting nor retching occurred after the first dose, so that the action of the drug must be looked on as wonderful." Every other treatment had failed before the cocaine was tried.

Diseases of the Uterus Treated by Fluids.

At the medical Congress at Nancy, M. Gairal, senior, presented an apparatus which he calfed a uterine basin, the object of which was to check uncontrollable vomiting in pregnant women, and to support the womb, which had become too heavy, by bringing it in permanent contact with a liquid which would cause local anæsthesia. M. Gairal referred to the question of leucorrhœa, on which gynæcologists were not agreed. He adopted a local treatment by a special method based upon the disposition of the vaginal mucous membrane, and the use of a vegetable charcoal powder introduced by means of a small insufflator.

How to Administer Quinine in Malarial Intermittent Fevers.

The following, though not new, has proved of such good service in several hundred cases of malarial fevers which came under our care, that we deem it of sufficient importance for publication. This way of administering the anti-periodic was suggested to us a number of years ago by our friend, Dr. H. D. Schmidt, who claims to have gotten it from the late Prof. G. B. Wood, of Philadelphia:

In intermittent fever always give the quinine in the intermission, the first dose twelve hours before the expected paroxysm, a second dose six hours after the first, and a third dose three hours after the second; given in this way the dose need seldom exceed five grains.

The Local Treatment of Syphilitic Affections.

M. Gilles, in a communication to the Biological Society (*Le Progrès Médical*, 24th July, 1886), on the microbic nature of local syphilitic affections, deals with the treatment of them. He has obtained excellent results by local baths to the affected parts. He has found this method succeed where general treatment had failed. Especially he has noted the results in palmar and plantar psoriasis which has been either early or late in appearing. He uses a solution of mercury, and gives the local bath for ten minutes. Crusts have to be removed to allow the parasiticide free action.

Ulexine.

It is curious that the common furze, or Ulex Europæus, should have been found to yield an alkaloidal substance; for it has been so frequently examined chemically in order to ascertain its nutritive qualities that one would have thought an active alkaloid could not have escaped detection. However, Mr. Gerrard has extracted an alkaloid that is very soluble in dilute hydrochloric acid, forms long oblique prismatic crystals, readily soluble in chloroform, and giving with ferric chloride a deep-red color. The physiologi-

cal action has not yet been worked out, but it has been found that the alkaloid has a paralytic action on frogs.

Electrolysis for Nævus.

Dr. A. Mayor, of Geneva, published an interesting case of an erectile tumor (a nævus of the cutaneo-subcutaneous variety) on the back, in a girl, aged 10 months, where he successfully tried electrolysis. The number of sittings was two; the duration of each about two minutes. The dose of the current was only two milliampères (from four cells of Leclanché's battery). On examination of the patient about four years later, not a trace of the nævus (which originally was of the size of a nut) was detected.

Treatment of Acne.

Hutchinson claims that ninety per cent. of all forms of acne is due to some hyperæmic condition of the genital organs, basing his conclusions mainly upon the fact that the disease makes its appearance at puberty. He successfully treats cases that persistently resist internal medication by the use of the cold urethral sound in the male, and the hot vaginal douche in the female, conjoined with a placebo. Beneficial results are secured in one to two weeks, and a cure in a month or two.

Tribromide of Allyl.

This compound, which has been known to the chemical world since 1857, has been found to be of value in medicine, in the treatment of hysteria, infantile convulsions, angina, and asthma. Dr. de Fleury administers it in five-minim doses enclosed in capsules, from ten to twenty minims being taken by the mouth in the twenty-four hours; the drug may be injected under the skin in doses of from two to four drops, dissolved in one or two cubic centimetres of ether.

Thrush, or Sore Mouth of Infants,

Is often due to the rough and careless swabbing out of the mouth of the child by the nurse, who uses the corner of a coarse towel, and proceeds as if she were scrubbing the kitchen floor or back stairs. In Prague, since Obstein has forbidden the washing of the mouths of infants born under his care, stomatitis has almost disappeared from the lying-in, whereas previously 52 per cent. of the infants born there, and under ten days old, were afflicted.

Hypodermic Solution of Quinine.

Where it is necessary to administer quininine subcutaneously, the following formula is recommended by Dr. S. Burt, as being as little irritating as possible:

℞.	Quiniæ bisulphatis,	ʒj.
	Acidi borici,	gr. ij.
	Morphiæ sulphatis,	gr. ¼.
	Aquæ destillatæ,	ʒj.

Sig.—For hypodermic use. One drachm contains seven and half grains of quinine.

Anodyne for Vesical Irritation.

Dr. Copeland recommends the following as an injection for the chronic inflammation of the neck of the bladder, in old men with enlarged prostates: Ten grains of the benzoate of soda to one ounce of water, to which is added 20 or 30 drops of the green tincture of gelsemium. This is warmed, and injected into the bladder when the pain is severe. It should be retained for 20 or 30 minutes, and then either evacuated or drawn off.

Tinea Tonsurans.

Dr. Van Harlingen (*Medical Times*, August 20) gives the following new formulæ:

℞.	Potassii iodidi,	ʒss.	
	Liq. potassæ,	ʒj,	M.

The hair is to be closely clipped and this sopped on to the scalp, with a pledget of lint, once daily; when dry, the following solution should be applied at the same points:

℞.	Hydrargyr. bichlor.,	gr. iij.	
	Aquæ,	ʒj.	M.

Cough Mixture.

Dr. H. C. Wood (*Therapeutic Gazette*) recommends the following as an excellent sedative cough mixture:

℞.	Pot. citrat.,	ʒj.	
	Succi. limon.,	ʒij.	
	Syr. ipecac,	ʒss.	
	Syr simplicis, ad.	ʒvj.	M.

Sig.—ʒss. four to six times a day.

Paregoric may be added when there is much cough or irritability of the bowels.

Mixture for Asthma.

The following prescription is much used by Dr. Fothergill in the treatment of asthmatic patients:

℞.	Amm. iodidi,	ʒij.	
	Amm. bromidi,	ʒiij.	
	Syr. tolu,	ʒiij.	
	Tinct. lobeliæ,	ʒv.	M.

Dose.—A teaspoonful.

Ready Treatment of Gleet.

Dr. Robt. T. Morris (*Kansas City Med. Index*) advises equalization of the urethra throughout its extent either by section or dilatation. This is to be followed by an injection of

℞.	Bismuthi subnit.,	℥j.
	Glycerinæ,	f℥j.
	Aquæ,	f℥ij.

M. S.—Inject three or four drams before retiring.

This is to be passed as far back as possible by rubbing the finger backward along the urethra; after the greater part has escaped, the meatus should be closed by a small wad of cotton. This injection should be continued until no further discharge is noted, which may be as early as the third injection, but this must be repeated two or three times at intervals of a week or ten days.

Gonorrhœal Rheumatism.

Bartholow uses small blisters about, but not over, the joint. He derives the best results from the use of tincture of iron internally. The green iodide of mercury, one-twentieth to one-twelfth of a grain thrice daily, with the sixth to a quarter of a grain of belladonna or minute doses of the bichloride, with iron and blisters, are useful.

Creasote a Specific for Erysipelas.

Six to twenty drops of creasote to an ounce of water is regarded by a contributor to the St. Louis *Medical Joarnal* as a specific for erysipelas. He applies it on cloths soaked in the solution, and says that in the treatment of hundreds of cases but one was fatal, and that in an old and decayed system.

For Myalgia.

Professor Bartholow (*Coll. and Clin. Rec.*) recommends the following liniment for myalgia:

℞.	Chlor. hyd.,	℥j.	
	Lin. sapon.,	℥ij.	M.

News and Miscellany.

Ninth International Medical Congress.

Circular no. 2.

The Ninth International Medical Congress will assemble in the city of Washington, the capital of the United States, on Monday, September 5th, 1887, at 12 o'clock noon, in accordance with the arrangements made at Copenhagen in August, 1884.

Patrons.

The President of the United States, the Hon. Grover Cleveland.

The Secretary of State, the Hon. Thomas F. Bayard.

The President of the Senate of the United States, the Hon. John Sherman.

The Speaker of the House of Representatives of the United States, the Hon. John G. Carlisle.

PROPOSED OFFICERS OF THE CONGRESS.

President.—Nathan S. Davis, M. D., LL. D., Professor of the Principles and Practice of Medicine and of Clinical Medicine, Chicago Medical College, and of Mercy Hospital, Chicago, Illinois.

Vice-Presidents, as far as appointed.—McCall Anderson, M. D., London, England; Mr. Thomas Annandale, Professor of Clinical Surgery, Edinburgh University, Edinburgh, Scotland; Professor Dujardin-Beaumetz, M. D., Paris France; Cuthbert Hilton Golding-Bird, M. D., Professor of Physiology, Guy's Hospital, London, England; Professor Carl Braun, M. D., Vienna, Austria; William Brodie, M. D., Emeritus Professor of Principles and Practice of Medicine and Clinical Medicine, Detroit College of Medicine, Detroit, Michigan; W. H. Dawson, M. D., Professor of Surgery and Clinical Surgery, Medical College of Ohio, Cincinnati, Ohio; Thomas M. Dolan, M. D., Halifax, England; F. R. Frazer, M. D., Professor of Materia Medica and Therapeutics, University of Edinburgh, Edinburgh, Scotland; J. A. Grant, M. D., Ottawa, Canuda; J. A. S. Grant, M. D., Cairo, Egypt; A. L. S. Gusseraw, M. D., Professor of Obstetrics, Berlin, Prussia; Dr. Hans Ritter von Hebra, Vienna, Austria; Dr. E. Klein. London, England; Mons. Le Baron H. Larrey, Paris, France; Sir William MacCormac, Surgeon St. Thomas' Hospital, London, England; Mr. George B. Macleod, Professor of Surgery, Glasgow, Scotland; John S. McGrew, M. D., Honolulu, Hawaiian Islands; E. M. Moore, M. D., LL. D., Rochester. New York; Professor von Monseil, Bonn, Prussia; Dr. Müller, Berlin, Prussia; William Murrell, M. D., London, England; Charles D. F. Phillips, M. D., M. R. C. S., late Lecturer on Materia Medica and Therapeutics, Westminster Hospital, London, England; Mr. Richard Quain, Professor of Anatomy, London, England; Tobias G. Richardson, M. D., Professor of General and Clinical Surgery, Medical Department, Tulane University, New Orleans, Louisiana; Mons. P. Ricord, Paris, France;

Professor John Burdon Sanderson, M. D., London, England; Lewis A. Sayre, M. D., Professor of Orthopedic and Clinical Surgery, Bellevue Hospital Medical College, New York; Dr. Mariano Semmola, Professor of Experimental Therapeutics, University of Naples, Italy; Dr. Leopold Servais, Antwerp, Belgium; J. M. Toner, M. D., Washington, D. C.; Dr. P. G. Unna, Hamburgh, Germany; Professor F. Winckel, Dresden, Saxony; The President of the American Medical Association; the Surgeon-General of the United States Army; the Surgeon-General of the United States Navy.

Secretary-General.—John B. Hamilton, M. D., Supervising Surgeon-General of the United States Marine Hospital Service; Professor of Surgery, Georgetown University, D. C.; Professor of Surgery, Chicago Polyclinic.

Treasurer.—E. S. F. Arnold, M. D., M. R. C. S., Newport, Rhode Island.

Chairman of the Finance Committee.—Richard J. Dunglison, M. D., Philadelphia, Pennsylvania.

Chairman of the Executive Committee.—Henry H. Smith, M. D., LL. D., Emeritus Professor of Surgery in the University of Pennsylvania, Philadelphia, Pennsylvania.

Chairman of the Committee of Arrangements.—A. Y. P. Garnett, M. D., Emeritus Professor of Clinical Medicine, Columbia University, Washington, D. C.

The Congress will consist of such members of the Regular Medical Profession as shall have registered and taken out their ticket of admission, and of such other scientific men as the Executive Committee of the Congress shall deem it desirable to admit. The books for the registration of members will be open from 9 a. m. to 5 p. m., on Thursday, September 1, 1887, and on each subsequent day during the session, under the charge of the "*Reception Committee.*" Any member desiring to anticipate this registration can apply by letter to the Secretary-General and forward his dues, with his address in full, when a receipt will be returned.

The dues for membership for residents of the United States will be ten dollars ($10.00). There will be no dues for members residing in other countries. Each member will be entitled to receive a copy of the "*Transactions*" of the Congress, when published by the Executive Committee.

The general sessions of the Congress will be devoted to the transaction of business and addresses and communications of general scientific interest, by members appointed by the Executive Committee. A printed "programme" of the sessions will be presented to each member on registering. A printed "Order of Business" for each day will also be issued.

The work of the various sections will be directed by the president of the section, and the order will be published in a daily programme for each section. Questions and topics that have been agreed on for discussion in the sections, shall be introduced by members previously designated by the titular officers of each section. Members who shall have been appointed to open discussions, shall present to the secretaries of the section, in advance, statements of the conclusions which they have formed as a basis for the debate.

Brief abstracts of papers to be read in the sections shall be forwarded to the secretaries of the proper section on or before *April* 30, 1887. These abstracts shall be treated as confidential communications, and shall not be published before the meeting of the Congress. Papers relating to topics not included in the list of subjects proposed by the officers of the sections, may be accepted after April 30, 1887, and any member wishing to introduce a topic not on the regular lists of subjects for discussion, shall give notice of the same to the Secretary-General, at least twenty-one days before the opening of the Congress. The titular officers of each section shall decide as to the acceptance of such proposed communications, and the time for their presentation. No communication shall be received which has been already published or read before a society.

The official languages of the Congress shall be English, French and German. Each paper or address shall be printed in the "*Transactions*" in the language in which it was presented. Preliminary abstracts of papers and addresses shall also be printed in the language in which each is to be delivered. All discussions shall be printed in English.

The officers of the Congress and the officers of the sections, including all foreign officers, will be nominated to the Congress by the Executive Committee, at the opening of the first session. A partial list of the officers to be nominated (except the members of Council of the different sections, the list of whom is at present imperfect), is offered herewith.

The Executive Committee cordially invites members of the regular medical profession, and men eminent in the sciences collateral to medicine, in all countries, to participate, in person or by papers, in the work of this great humanitarian assembly. Communications relating to ap-

pointments for papers to be read in Congress should be addressed to Dr. John B. Hamilton, Secretary-General of the Ninth International Medical Congress, Washington, District of Columbia. All questions or communications connected with the business of the Executive Committee should be addressed to Dr. Henry H. Smith, Chairman of the Executive Committee of the Ninth International Medical Congress, Philadelphia, Pennsylvania. Gentlemen named in any position in the Congress are requested to notify the Chairman of the Executive Committee, as soon as practicable, of any error in the name, title, or address in this circular.

Ladies in attendance with members of the Congress, and those invited by the "Reception Committee," may attend the general sessions of the Congress when introduced by a member. They will also be invited to attend the Social Receptions. The Executive Committee reserves the right to invite distinguished persons to any or all the meetings of the Congress. The attendance of medical students and others interested in the work of the various sections or in the general addresses delivered in the Congress, will be permitted, on the recommendation of the Secretary-General or the officers of a Section, on their taking out from the Registration Committee a general ticket of admission, fee one dollar ($1.00); but such persons can not take part in the proceedings.

All communications and questions relating to the special business of any Section, must be addressed to the President or one of the Secretaries of that Section. As many details of the Congress and numerous appointments of officers are yet to be completed, other circulars will be issued from time to time, as circumstances may demand.

The following is the list as at present completed:

Executive Committee of the Congress.—Henry H. Smith, M. D., LL. D., Chairman; N. S. Davis, M. D., LL. D.; John B. Hamilton, M. D.; E. S. F. Arnold, M. D.; Richard J. Dunglison, M. D., Secretary; Abram B. Arnold, M. D.; William T. Briggs, M. D.; De Laskie Miller, M. D., Ph. D.; James F. Harrison, M. D.; F. H. Terrill, M. D.; William H. Pancoast, M. D.; John H. Callender, M. D.; Alonzo B. Palmer, M. D., LL. D.; J. Lewis Smith, M. D.; E. Williams, M. D.; S. J. Jones, M. D., LL.D.; William H. Daly, M. D.; A. R. Robinson, M. D.; Joseph Jones, M. D.; Albert L. Gihon, M. D.; John P. Gray, M. D., LL. D.; Jonathan Taft, M. D.; Frederick S. Dennis, M. D.; A. Y. P. Garnett, M. D.

PRESIDENTS OF SECTIONS.

General Medicine.—Abram B. Arnold, M. D., Professor of Clinical Medicine, College of Physicians and Surgeons, Baltimore, Md.

General Surgery.—William T. Briggs, M. D., Professor of Surgery, University of Nashville, Nashville, Tenn.

Military and Naval Surgery and Medicine.—Henry H. Smith, M. D., LL. D., Emeritus Professor of Surgery, University of Pennsylvania, and formerly Surgeon-General of Pennsylvania, Philadelphia, Pa.

Obstetrics.—DeLaskie Miller, M. D., Ph. D., Professor of Obstetrics, Rush Medical College, Chicago, Ill.

Gynæcology.—James F. Harrison, M. D., Professor of Obstetrics, etc., University of Virginia, Va.

Therapeutics and Materia Medica.—F. H. Terrill, M. D., Professor of Therapeutics, University of California, San Francisco, Cal.

Anatomy.—William H. Pancoast, M. D., Professor of General, Descriptive, and Surgical Anatomy, Medico-Chirurgical College, Philadelphia, Pa.

Physiology.—John H. Callender, M. D., Professor of Physiology and Psychology, University of Nashville, Nashville, Tenn.

Pathology.—Alonzo B. Palmer, M. D., LL. D., Professor of Pathology, University of Michigan, Ann Arbor, Mich.

Diseases of Children.—J. Lewis Smith, M. D., Professor of the Diseases of Children, Bellevue Hospital Medical College, New York, N. Y.

Ophthalmology.—E. Williams, M. D., Professor of Ophthalmology, Miami Medical College, Cincinnati, Ohio.

Otology.—S. J. Jones, M. D., LL. D., Professor of Ophthalmology and Otology, Chicago Medical College, Chicago, Ill.

Laryngology.—William H. Daly, M. D., Pittsburgh, Pa.

Dermatology and Syphilis.—A. R. Robinson, M. D., Professor of Dermatology, New York Polyclinic, and of Histology and Pathological Anatomy, Woman's Medical College of the New York Infirmary, New York, N. Y.

Public and International Hygiene.—Jos. Jones, M. D., Professor of Chemistry and Clinical Medicine, Tulane University; ex-President Board of Health, New Orleans, Louisiana.

Medical Climatology and Demography.—Albert L. Gihon, M. D., Medical Director U. S. Navy.

Psychological Medicine and Nervous Diseases.—John P. Gray, M. D., LL. D., Pro-

fessor of Psychological Medicine and Medical Jurisprudence, Bellevue Hospital Medical College, Utica, N. Y.

Dental and Oral Surgery.—Jonathan Taft, M. D., Professor of Dental and Oral Surgery, University of Michigan, Ann Arbor, Mich., Cincinnati, Ohio.

VICE-PRESIDENTS OF SECTIONS.

General Medicine.—W. W. Cleaver, M. D., Kentucky; J. A. Octerloney, M. D., Kentucky; P. G. Robinson, M. D., Missouri; Thomas F. Rochester, M. D., New York; Preston B. Scott, M. D., Kentucky.

General Surgery.—Moses Gunn, M. D., Illinois; J. W. Hamilton, M. D., Ohio; W. H. Hingston, M. D., Canada; James M. Holloway, M. D., Kentucky; J. C. Hutchison, M. D., New York; N. S. Lincoln, M. D., District of Columbia; Donald MacLean, M. D., Michigan; Donald Macrea, M. D., Iowa; M. Storrs, M. D., Connecticut.

Military and Naval Surgery and Medicine.—C. J. Cleborne, M. D., United States Navy; E. H. Gregory, M. D., Missouri; Frank H. Hamilton, M. D., New York; W. T. Hord, M. D., United States Navy; Frederick Hyde, M. D., New York; G. L. Porter, M. D., Connecticut; Wm. E. Taylor, M. D., United States Navy; B. A. Watson, M. D., New Jersey.

Obstetrics.—Gustav Braun, M. D., Austria; P. Budia, M. D., France; J. Galabin, M. D., England; John Goodman, M. D., Kentucky; W. M. Knapp, M. D., Nebraska; R. L. Sibbet, M. D., Pennsylvania; Isaac E. Taylor, M. D., New York.

Gynæcology.—N. Bozeman, M. D., New York; Henry O. Marcy, M. D., Massachusetts; T. A. Reamy, M. D., Ohio; H. R. Storer, M. D., Rhode Island.

Therapeutics and Materia Medica.—Henry M. Field, M. D., New Hampshire; Albert Frické, M. D., Pennsylvania; George Gray, M. D., Ireland.

Anatomy.—C. W. Kelly, M. D., Kentucky; Samuel Logan, M. D., Louisiana.

Physiology.—

Pathology.—Andrew Fleming, M. D., Pennsylvania; J. B. Johnson, M. D., Missouri; Henry F. Lyster, M. D., Michigan.

Diseases of Children.—William B. Atkinson, M. D., Pennsylvania; William G. Booker, M. D., Maryland; Cadet de Gassicourt, France; Edward Hunoch, Prussia; Adoniram B. Judson, M. D., New York; J. P. Owen, M. D., Massachusetts; Eustace Smith, M. D., England; Charles West, M. D., England; Joseph E. Winters, M. D., New York.

Ophthalmology.—A. W. Calhoun, M. D., Georgia; J. J. Chisholm, M. D., Maryland; P. D. Keyser, M. D., Pennsylvania; Dudley S. Reynolds, M. D., Kentucky.

Otology.—

Laryngology.—M. F. Coomes, M. D., Kentucky.

Dermatology and Syphilis.—James M. Keller, M. D., Arkansas; John V. Shoemaker, M. D., Pennsylvania.

Public and International Hygiene.—A. Nelson Bell, M. D., New York; John Berrien Lindsley, M. D., Tennessee; J. N. McCormack, M. D., Kentucky; J. F. Y. Paine, M. D., Galveston, Texas; Benjamin W. Richardson, M. D., England; John Simon, M. D., England; J. W. Thudicum, M. D., England.

Medical Climatology and Demography.—Dr. A. Chervin, Paris, France; Traill Green, M. D., Pennsylvania; John H. Hollister, M. D., Illinois.

Psychological Medicine.—Julius Athaus, M. D., England; R. H. Chase, M. D., Pennsylvania; Eugene Grissom, M. D., North Carolina; John C. Hall, M. D., Pennsylvania; P. A. Hooper, M. D., Arkansas; J. S. Jewell, M. D., Illinois; S. S. Schultz, M. D., Pennsylvania.

Dental and Oral Surgery.—W. W. Allport, M. D., Illinois; S. W. Dennis, M. D., California; C. L. Ford, M. D., Michigan; H. L. McKellops, M. D., Missouri; A. T. Metcalf, M. D., Michigan; W. H. Morgan, M. D., Tennessee; A. L. Northrop, M. D., New York.

SECRETARIES.

General Medicine.—J. W. Chambers, M. D., Baltimore, Maryland.

General Surgery.—Dudley P. Allen, M. D., Cleveland, Ohio; Carl Mayde, M. D., Germany; J. R. Weist, M. D., Richmond, Ind.; A. H. Wilson, M. D., South Boston, Mass.

Military and Naval Surgery and Medicine. J. McF. Gaston, M. D., Atlanta, Georgia; E. A. Wood, M. D., Pittsburg, Pa.

Obstetrics.—A. Charpentier, M. D., Paris, France; T. Felsenreich, M. D., Vienna, Austria; W. W. Jaggard, M. D., Chicago, Ill.; John Williams, M. D., London, England.

Gynæcology.—Ernest W. Cushing, M. D., Boston, Mass.

Therapeutics.—Frank Woodbury, M. D., Philadelphia, Pa.

Anatomy.—Henry Morris, M. D., Philadelphia, P.

Physiology.—R. W. Bishop, M. D., Chicago, Ill.

Pathology.—H. M. Biggs, M. D., New York, N. Y.; I. N. Himes, M. D. Cleveland, Ohio.

Diseases of Children.—

Ophthalmology.—S. C. Ayres, M. D., Cincinnati, Ohio.

Otology.—S. O. Richey, M. D., Washington, D. C.

Laryngology.—William Porter, M. D., St. Louis, Missouri.

Dermatology.—W. T. Corlett, M. D., Cleveland, Ohio; F. E. Daniel, M. D., Austin, Texas.

Public and International Hygiene.—Geo. H. Rohé, M. D., Baltimore, Md.; Walter Wyman, M. D., U. S. Marine Hospital Service, New York, N. Y.

Climatology and Demography.—Charles Denison, M. D., Denver, Colorado; James F. Todd, M. D. Chicago, Illinois.

Psychological Medicine.—E. D. Ferguson, M. D., Troy, N. Y.; E. Landolt, M. D. (Berlin, Prussia), Paris, France.

Dental and Oral Surgery.—Edward A. Bogue, M. D., New York, N. Y.; S. F. Rehwinkle, M. D., Chillicothe, Ohia.

Committee of Arrangements, Washington, D. C.—A. Y. P. Garnett, M. D., *Chairman;* J. M. Toner, M. D., *Vice-Chairman;* C. H. A. Kleinschmidt, M. D., *Secretary;* D. C. Patterson, M. D., *Treasurer.*

Executive Committee.—Drs. A. Y. P. Garnett, J. M. Toner, N. S. Lincoln, C. H. A. Kleinschmidt, Surgeon-General F. M. Gunnell, M. D., U. S. Navy; Surgeon-General Robert Murray, M. D., U. S. Army; Supervising Surgeon-General J. B. Hamilton, M. D., U. S. Marine Hospital Service; Chief Medical Purveyor J. H. Baxter, M. D., U. S. Army.

Committee on Congressional Legislation.—Dr. A. Y. P. Garnett, *Chairman.*

Committee on Finance.—Dr. G. L. Magruder, *Chairman.*

Committee on Printing.—Dr. J. B. Hamilton, *Chairman.*

Committee on Reception.—Dr. J. M. Toner, *Chairman.*

Committee on Entertainments.—Dr. N. S. Lincoln, *Chairman.*

Committee on Transportation.—Dr. J. W. H. Lovejoy, *Chairman.*

Committee on Place of Meeting for Congress and Sections.—Dr. D. C. Patterson, *Chairman.*

By order of the Executive Committee of the Congress.

HENRY H. SMITH, M D.,
Chairman.

RICHARD J. DUNGLISON, M. D.,
Secretary.

American Academy of Medicine.

Tenth Annual Session at Pittsburgh, Pa., October 12 and 13, 1886.

The meeting was called to order by Dr. R. Stanbury Sutton, the President. Dr. Purvis, A. M., M. D., pastor of the First Presbyterian church, in which the meeting was held, led in prayer.

After considerable routine business, a paper was read by W. Dimplison, A. M., M. D., of Philadelphia, on "The Laws Regulating Practice in the Different States."

F. N. Gerrish, A. M., M. D., of Portland, Maine, followed with a paper. Subject, "The Best Equipment for Medical Study."

The special committee appointed to report on the best preliminary education for medical students next made its report. The chairman, F. N. Gerrish, A. M., M. D., spoke strongly in favor of a classical education for all students, and referred with feeling to the prostitution of the medical profession by colleges which were little more than mere speculators.

John D. Kelley, A. M., M. D., of Lowville, N. Y., read on "The Status of Medical Education in the United States."

L. P. Bush, A. M., M. D., of Wilmington, Delaware, read on "The Advantages of a Classical Education to the Medical Student and Physician." He took decided ground in favor of a classical education. W. H. Pancoast, A. M., M. D. ,of Philadelphia, thought that too much Latin and Greek were studied at a tender age. He thought youths should study more French and German. He referred to the German system of education. They are the most classical students in the world.

J. Chester Morris, A. M., M. D., of Philadelphia, next read on "Prolonged Gestation," relating interesting cases.

Traill Green, A. M., M. D.. Easton, Pa., "The Duties of Physicians to Each Other."

A. C. Kemper, A. M., M. D., Cincinnati, "A Christian Education the Best Preparation for the Practice of Medicine."

Henry O. Marcy, A. M., M. D., "Is Modern Wound Treatment Scientific?"

Virgil P. Gibney, A. M., M. D., of New York, "Treatment and Management of Tubercular Spondylitis."

Nathan Allen, A. M., M. D., Lowell, Mass., "Physical culture in Amherst College." He favored gymnastics over feats of ball, rowing, etc., which only developed certain muscles.

Geo. E. Stubbs, A. M., M. D., Philadelphia, "What should Physicians Advise as to the Education of Young Women?"

The following new members were elected: J. G. Sloane, A. M., M. D., Monongahela City; M. H. Borland, A. M., M. D., Pittsburgh; C. H. von Klein, A. M., M. D., Dayton, Ohio; A. B. Threasher, A. M., M. D., Cincinnati; Philip Zenner, A. M., M. D., Cincinnati; Richard Hogsden, A. M., M. D., Abington, N. Y.; W. B. Canfield, A. M., M. D., Baltimore; E. Wirst, A. M., M. D., Chicago; L. Curtis, A. M., M. D., Chicago; R. I. Buntley, A. M., M. D., Pittsburgh; S. D. Jennings, A. M., M. D., Allegheny; W. D. Kearns, A. M., M. D., Pittsburgh; John Dubb, A. M., M. D., Pittsburgh; N. J. R. Klein, A. M., M. D., Greensburgh, Pa.; W. C. Shaw, A. M., M. D., Pittsburgh; J. C. Connell, A. M. M. D., Pittsburgh.

The nominating committee reported the following names:

President—L. P. Bush, A. M., M. D., Wilmington, Delaware.

Vice Presidents—R. I. Sibberts, A. M., M. D., Carlisle, Pa.; S. J. Jones, A. M., M. D., Chicago; P. S. Connor, A. M., M. D., Cincinnati; W. P. Gibney, A. M., M. D., New York.

Secretary and Treasurer—R. J. Dunglison, A. M., M. D., Philadelphia.

Assistant Secretary—Chester McIntyre, Jr., A. M., M. D., Pittsburgh.

Dr. R. Stansbury Sutton delivered the

PRESIDENT'S ADDRESS.

He welcomed the members of the Society to Pittsburgh on this, their first meeting west of the Alleghenies. This city is the gateway to the great Ohio valley, and as civilization went out through it westward on the bosom of "the beautiful river," so may ideas of a higher education for the physician in the United States, from your meeting here, spread out over this great western country.

In the United States the lives and health of 60,000,000 people are in the hands of the medical profession. This responsibility is too great for other than educated shoulders to bear. While there are many men of might in this noble profession of ours, yet there are many others absolutely destitute of both general and professional knowledge. The fact that venders of patent medicines become mlllionaires while many a diplomated doctor fails to obtain subsistence, proves that there is a growing dissatisfaction with the profession. The multiplication of medical mountebanks and peripatetic physicians strongly sustains this statement. The improper and unmanly methods to which many physicians resort to obtain practice shows that hunger is at the root of the struggle. These and similar evils demand attention. The cause first in injury is the number and nature of our medical schools. He referred with words of praise to the schools established during the first century of the nation's life. At the end of this first century the supply of schools and men exceeded the demand. Most of the excess came from a large number of small schools, whose deficiency prevented an honest competition with their more favored rivals. Necessity made them and their wares cheap. Financially, they have been failures, and their faculties have lost money. They found solace, however, for money spent by being dubbed "professor," and their incompetent graduates were compelled to become drummers for their alma mater, by bringing in the cases they could not master to their teachers. The medical men of other centres of population, hearing of this new manner of gaining practice, secured a charter, erected buildings, and proceeded to business. Medical mills multiplied until we have now 101 incorporated institutions, good and bad, in the United States. These are attended annually by 15,000 students, and graduate each year nearly one-half this enormous number. During the seventh decade of this century, 25,000 medical men were added to the list.

He recounted at length the evils resulting from this pernicious system of education, and recommended for its removal the only remedy —legislation.

He was Coming "Hindside Foremost."

Referring to the story of the young practitioner who mistook the anus of the child for the undilated os of the mother, the *South. Cal. Practitioner* says:

"This reminds us of a case we had in 1877. We were called in great haste to a case of confinement, and found in charge a well known Los Angeles midwife. She, in an excited manner, told us the baby was coming "hindside foremost," and that it was a little girl. The husband and wife and the neighboring women all looked in awe at the midwife who was able to so confidently foretell the sex. We examined, and found a face presentation. The midwife thought she had her finger in the vagina when it was in the child's mouth. The discomfiture of the old lady was complete when a ten-pound boy was born."

The Patient and the Doctor.

A peasant who was very ill and expected to die promised the doctor $50 if he saved his life. A fortunate turn of the disease en-

abled the doctor to pull his patient through, but when he presented his bill the peasant exclaimed:

"What a monstrous robbery! I'll never pay it!"

"But you set your own figures."

"Yes, but any jury will decide that I was too ill to transact business."

To Rapidly Heat Water.

A new form of vessel has been devised for heating water rapidly. It consists in studding the bottom of an ordinary metallic water vessel with copper rods, which pass through the bottom of the vessel into the water, where they are flattened out, and give up their heat very rapidly. By this means an experimenter has boiled one pint of water in a strong four-quart kettle weighing over six pounds, in fifty seconds.

Editorial Amenities.

Country Editor (to brother editor)—Ah! good morning, Brother Shears; glad to see you. And how are things up at Pigville?

Brother Shears—Flourishing just at present, but last month we had the hog cholera pretty bad.

Country Editor—I'm sorry to hear that. But you are looking well now, Brother Shears.

Labor Among Primitive Peoples.

The *Boston Med. and Surg. Journal* states states that in one of the largest book-stores of the "hub," the entire available force of the establishment was engaged for half a day in an ineffectual search for this work of Dr. Engelmann's in the department of political economy, attention being now so generally directed to [non-medical] labor questions.

Items.

—A "sandwich" man on Broadway, New York, carries the following legend on his sign: "Advertising is like hugging a pretty girl—it can't be overdone."

—In the last five years Billroth has performed operations on the stomach in thirty-two cases, with nineteen fatal results. Out of fifteen gastrectomies for cancer, there were seven recoveries.

—In the surgical clinic at Jefferson College, Philadelphia, lately, Professor Brinton remarked that when a man shaved or a woman did up her back hair, it was a certain sign they would get well.

—Toothache from decayed teeth is said by a Swiss authority to be relieved promptly by cotton-wool moistened with a mixture of equal parts of camphor and chloral, and a fifth as much cocaine.

—The papers that hoist before the public the figures of their circulation—apt to be fathomless lies—bear the same relation, remarks a lay contemporary, to admirable journalism that John L. Sullivan, whose circulation is much greater than Oliver Wendell Holmes's, bears to that intellectual autocrat.

—President Dwight, of Yale, whose back shows a sharp curve as he walks, says: "A little girl, after watching me walk for a while, remarked: 'Mamma, I think he is the stoopedest man I ever did see.'" The worthy president always enjoys a good story, even though it be at his own expense.

—A new tanning material, which, in the opinion of the *Leder Interessent*, is destined to play a leading *rôle* in the tanning industry of the future, is the tanekohe bark, from New Zealand, which is at present employed in Europe only at Grenoble, where it is applied to the dyeing of gloves. It contains 26.66 per cent. of tannic acid.

—At Walton (N. Z.) a family named Fitzimons—father, mother, and two children—were suffering severely from poisoning. A doctor administered remedies, and it was discovered that some gruel, of which all had eaten, had been made of meal which had been mixed with arsenic for the purpose of poisoning rats. The children were in a critical state, but the father and mother were in a fair way of recovery.

—A doctor having written to Mr. Gladstone pointing out the enormous number of deaths from consumption, and stating that the disease is "within our control," concluding by asking if the government is prepared to grant funds for investigating the matter, has been referred to the Royal Society, which has four thousand pounds a year placed at its disposal in aid of scientific investigations.

—A lady writes to the *Boston Journal:* "Our little two-year-old boy is very fond of medicine. No matter what the kind, he takes it with evident relish, and teases for it on all occasions. The other day he came running in and said he was sick and tired, and his leg ached, and he must have some. To pacify him, his mother gave him a teaspoonful of cough syrup. After lapping out the spoon, he looked roguishly up at her, and said in an appealing tone, 'Got two legs, mamma; mus' have anozer spoonful for ze ozer leg.'"

Pallas Syringe."

[From the *London Medical Record.*]
"It is a useful Instrument, and will be a formidable rival to the ordinary vaginal douche,"

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

105-15556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

CHOREA AND ITS TREATMENT BY CIMICIFUGA RACEMOSA.

BY HIRAM CORSON, M. D.,

Of Conshohocken, Pa.

In the *Maryland Medical Journal* of April 24, 1886, there is an article on chorea by Spencer M. Free, M. D., of Baltimore, which came to me a few days ago, and which has induced me to offer your readers some remarks in reference to its treatment.

This excellent paper by Dr. Free, so replete with information in all that relates to the causes, symptoms, pathology, and treatment of the disease as known by authors of the present time, is well worthy of attentive perusal. But so greatly was I amazed not to find the cimicifuga—black snake-root—spoken of as a remedy, though he remarks, "without a careful search we have come upon thirty-nine forms of treatment," that I am impelled to offer him one more remedy, a remedy greatly to be preferred to the one of which he says, "The one remedy which is the main reliance of the great majority of practitioners is arsenic." Quite half a century ago there were three country physicians in Pennsylvania who attracted attention by their valuable contributions to the *Am. Journal of the Medical Sciences*, in relation to their treatment of diseases so frequently met with by physicians. They were Samuel Jackson, of Northumberland; Ezra Michener and Jesse Young, of Chester county. Their articles were eagerly looked for, and their advice and modes of treatment thankfully received. Many a young practitioner was helped and cheered by their valuable counsel, their truthful reports of cases of illness, and the value of remedies as witnessed by them; and thus were enabled ofttimes to bring comfort and health to patients by means and appliances before unknown to them. At present I have only to speak of the last-named. Writers from the days of Cullen in the last century to the present time agree in their general history of the disease, their inability to refer it to any special cause or to discover by post-mortem examination characteristic pathological changes. They all speak, too, of the same remedies—of their utility in some cases, their utter inutility in others—of cases lasting for months and years, in defiance of the one remedy by all of them deemed the best, namely, arsenic.

Although I have used cimicifuga racemosa in every case which has come to me in more than fifty years, and always successfully in a brief time, I feel that justice would not be done the subject by giving my experience without preceding it by the experience of Dr. Jesse Young. It is a matter of regret that your space will not allow me to give his whole article, his thoughts and reflections on the subject, instead of merely giving briefly his cases.

The *Am. Journal of Medical Sciences* of February, 1832, on page 310, has "Observations on the Remedial Powers of the Cimicifuga Racemosa in the Treatment of Chorea," by Jesse Young, M. D., from which I take the following notice of four cases. He says:

"It is a very popular medicine both for man and beast. it is used in infusion or decoction chiefly as a pectoral medicine. . . . .

Who first used it in chorea I have no means of learning.

"1. Four years ago a son of Joseph Fairlamb, aged 11 years, was attacked; one side was affected and was in almost constant motion, except when he was asleep. During more than four months his physician was using all his efforts to arrest it, but without the least benefit resulting. An *old woman* then told him that the black snake-root would cure it. She told him to give a teaspoonful (of the root) three successive mornings, then omit three, and so on, till he gave it nine times. He told me when he had given six portions the boy was almost well. and when he had taken his nine portions he was perfectly cured, and has so remained.

"2. In the month of March of the present year a daughter of Mr. Isaac Hall was attacked. His physician was called, and after treating it for a month without any good resulting, his physician agreed to his using the snake-root, of which he had heard, as used in the above case. After taking three portions, her symptoms were much improved; and after six doses she was entirely well; the other three were, however, given, and she remains well at this time. In this case it puked severely almost every time it was given.

"In Mr. Fairlamb's boy, it did not vomit, but several times, though not always, made him quite sick.

"I now determined to watch its effects and ascertain whether it would cure by its own intrinsic properties (not as an emetic) or whether these reported cures might not be mere coincidences, and, in reality, the consequences, perhaps, of former treatment.

"3. On the 12th of September I was requested to see Mrs. ———, aged nineteen years; married two months; believed *not to be pregnant.*

"The affection commenced two weeks ago, but so gradually that she was not aware of anything serious being the matter till within a day or two, she has got so bad as to be almost constantly in motion with the left side; it does not prevent sleep; health good; could detect no cause, save that her father had been once affected, when a boy; in his case, caused by fright, and was cured, or got well, in two or three years, after using much medicine without benefit; but believes it was the cold bath that cured him at last,

"I ordered an emetic of tart. ant. with a view to its impression rather than its evacuant effect, to be followed by calomel and jalap next day; and after this to purge every morning with cream tart. et jalap till I could procure the snake-root. On the 20th, I took a quantity of it to her, but was startled when I found the affection had extended to the other side, and was tenfold aggravated; her arms, her legs, her head, face, tongue, and every muscular part of the system appeared to be in continual, irregular, alternate motion; she could only, with great difficulty, articulate so as to be at all intelligible; the power of deglutition was suspended to a very great extent; she could not walk one step, nor support herself erect without assistance, nor could she sleep, day or night, on account of the constant twitching and jerking of the muscles. Such was her condition when she began to take the snake-root—one teaspoonful of the powder three times a day, before eating—but if it sickened her when taken on an empty stomach, to take it after instead of before meals, in any pleasant vehicle, as molasses, preserves, etc. On the 25th, I visited her again and found a great change for the better—had walked the day before several hundred yards, could speak and swallow as well as ever she could, and could sleep well at night. Her arms were still somewhat affected. Ordered the medicine discontinued for two or three days, then used again as before.

"October 3 found her so well that a person who was not aware of her having the affection would not notice anything ailing her; a few more doses were used, once or twice a day, for a week, and she was well, and is so at this time."

His remarks are too long to copy here, but it never sickened if not taken on an empty stomach; did not at any time purge, sweat, or act as a diuretic, but "caused an uneasy feeling amounting to almost an ache through all her extremities every time she took it, which would continue from one to three hours; that *it alone cured* must be obvious to every one."

4. The fourth case spoken of by Dr. Young was told him by his friend, Dr. Gregg, who said: "I should have had a case to treat had it not been for the black snake-root." He had met a man in whose family he practiced who told him "his child had Saint Vitus' dance, and he had heard of Hall's daughter's case, and if the snake-root don't cure her I will call on you."

Dr. Gregg saw the man a short time after and learnt that the patient had been cured in a few days by the article.

There is much more in Dr. Young's article which would deeply interest your readers, but I must be content with merely adding his conclusion: "Neither *a priori* reasoning nor

professional erudition can ever direct us to the peculinr properties or effects of any of our vegetable productions; they can only become known from repeated trials and experiments. In this class exactly stands the cimicifuga racemosa, in chorea and probably in other nervous affections. Let it be fairly tried, and on these trials let its merits stand or fall."

The above was published fifty-four years ago last February, and yet to-day, in a paper published by a physician living in a city, a man conversant with medical literature, and earnest and diligent in his search for remedies useful in chorea, does not name it with his twenty-nine. Is this evidence that, tried on its merits, it has failed? Or is it not more probable that it has been but rarely tried, and that those who have tried it have failed to report, and thus it has not been brought to the notice of Dr. Free?

Be this as it may, I took Dr. Young at his word, gave it a trial of fifty years, and now report it almost if not quite a specific in chorea, and of great value in many other affections.

I ought to say here that Dr. Jesse Young was probably the first regular physician that ever used the black snake-root in chorea—at least the first who published an account of its use; for in a note by the editor appended to the communication, he says: "We are not aware of the remedial powers of the black snake-root having been noticed by any writer on the materia medica, but Dr. Physick informed us nearly ten years ago that he had known the plant, given in doses of ten grains every two hours, prove successful in the treatment of chorea in several instances."

Dr. Wm. Cullen, Professor of the Practice of Medicine in Edinburgh from 1776, for nearly twenty years, and whose "First Lines in the Practice of Medicine" was a text-book in the early part of this century in the University of Pennsylvania, does not speak of the cimicifuga as a remedy, but says: "Dr. Sydenham proposed to cure the chorea by alternate bleeding and purging. In some plethoric habits I have found some bleeding useful; but in many cases I have found repeated evacuations, especially by bleeding, very hurtful."

Dr. John Eberle, Professor of Materia Medica in Jefferson Medical College as early as 1828, and whose "Treatise on the Practice of Medicine," published in 1830, was then considered to he a most valuable work, names almost as many modes of treatment and different remedies as Dr. Free, and with as little confidence in any one of them. He wrote: "In a young lady, seized with chorea in consequence of suppressed catamenia, I directed her to be bled ʒxij, and to take a pill of ext. colocynth 3 grs., calomel gr. iss, tart. ant. $\frac{1}{10}$ gr. every night, and a small dose sulph. mag. every fourth day. In the course of two weeks she was bled four times, and the disease disappeared during the third week." Dr. Eberle did not name the snake root, had probably never heard of it, and I should probably have been led to resort to some one of the modes of practice spoken of by him, had it not been that the recommendation of the cimicifuga by Dr. Young met my eye. From that day to this I have relied on it alone, and in every case it has given speedy relief. I brought it to the notice of our County Medical Society, and some of the members can bear similar testimony to its control over the disease. This confirmation of Dr. Jesse Young's testimony might perhaps justify me in saying nothing more on the subject, but possibly the brief narration of a few of the many cases which have come under my care, will better satisfy your readers of the safety and value of the remedy that I offer them.

In June, 1836, Mrs. W., a young woman advanced to the middle of the third month of her first pregnancy, became ill with chorea, and I saw her on the first day of June. It was, I think, in 1834, that Dr. J. K. Mitchell called the attention of the profession to irritation of the spine as a cause of rheumatism and some other affections, and the good results of treatment derived from cups, leeches, and external irritation over the spinal column. Pustulation by tartar emetic ointment was very fashionable, and "disease of spine" was, like malaria now, a phrase used for nearly every departure from health. I find that from the first of June until the 16th, external irritation of the spine with tonics was mainly relied on in her treatment, and by this time she was confined to bed in a most pitiable and helpless condition. I then directed one teaspoonful tr. cimicifuga after each meal; her recovery was rapid, and I ceased attendance on the 12th, from which time she attended to her household duties, and passed through her confinement on December 15th, and had a good "getting up." I will now skip the cases of the next fourteen years.

Case 2. In 1850, a girl of eleven years, of rather unusual growth, was affected with chorea, and though living in Conshohocken, was taken to Newark, N. J., to the old family doctor. From the time of Dr. Hamilton until the time of which I write, the active

purgative practice he was zealous to promote, a practice to which I have already alluded, was everywhere resorted to by physicians to a greater or less degree, and the old family doctor put her under a full course of that treatment for three months, with a gradual reduction of health, and such an increase of the disease that when she was brought back by the mother, hopeless of cure, she was in a most pitiable state—I need not describe it, it paralleled Dr. Young's case. I was called on account of the mother being informed by a friend, whose child had been relieved of an attack by the snake root, advised by me. Her motions were almost incessant—even when asleep they were not wholly absent—speech and swallowing difficult, confined to bed, and with so idiotic an appearance that the mother, a woman of family pride, evidently dreaded her recovery, confident that her intellect would be impaired. I directed the infusion, made as before, from properly prepared roots. She began its use April 4, 1850. I ceased to attend her on the 30th, when she was walking out, but called again on the 4th of May and found her entirely well. Her health from this time was excellent. This case was the result, I think, of too close study at home, with no exercise such as children get when at school in the country, she not being allowed to attend the school to which the *workingmen's children* went. I will now skip the next twenty-five years, in which I had several cases, and speak of a few which have occurred since, or within the last ten years.

Case 3. On the 29th of April, 1875, I was asked to see a boy of about eleven years of age, who, though still going to school, had for a few weeks been affected with chorea, to a degree that caused children to laugh at him and sometimes mock him. He was able to eat quite well, and though his limbs were much affected and his face full of grimaces, had not been taken from the school. As the anxiety and efforts of the schoolroom are the prolific source of chorea in children, he was at once kept at home and put on the use of tinct. black snake-root (prepared by myself from good roots gathered at the proper time). My last visit to him, he being apparently well, was on the 15th of May, but the medicine was continued for two or three weeks longer, a dose or two daily. His recovery was complete.

Case 4. Allow me to report a case which I did not attend, but which was so like the one just reported in age and kinship and in its early symptoms, though so widely different in its course and in the long suffering which he endured, and in his final recovery by the use of the cimicifuga, that I think the two cases should be placed near to each other, to show the utter inutility of the remedies used by his physician, and the prompt and efficient action of the snake-root, used even without the supervision of a doctor.

In the early part of 1874 a boy in his eleventh year had an attack of chorea which followed a light attack of rheumatism of the right knee, from which he had suffered a month or two before. The chorea began with twitching of the right side. Very soon a physician was called, and by the end of a fortnight, then the beginning of June, he was unable to talk, had great difficulty in swallowing, could not feed himself, and was soon unable to continue in bed, so a bed was made on the floor for him; but even then so greatly did he twitch and jerk that he oftimes would roll out of it on to the floor. Remedies were tried in rapid succession during the coming winter and following spring without availing much, but yet he could swallow better, and could articulate so as to be understood. A small wagon was then built for him, in which he could lie at full length, and be dragged about by his friends or the neighbors' children. I need not go further into details; suffice it to say that for three years more he continued to be affected, but exercise in a carriage constructed to enclose his body, and with a rim on which he could rest his arms, and with rollers under it, which enabled him to move about his room, after some months invigorated him, he then being able to eat well, and he became able to walk out of doors. The cold bath was tried two weeks, then he was taken to Atlantic City during the bathing season, and was treated there in a regular hot-bath establishment. After that the electrical cure was tried, under the supervision of Dr. Playfair, of Philadelphia; but none of these things availed much. When at Atlantic City his appearance on the street when his parents were taking him a short distance to the hot-bathing establishment would immeately attract the attention of those who saw him, and lead to unpleasant remarks. I had several times seen him when he was being taken about in the small wagon, and was pained to witness his motions and contortions. Thus during more than four years he suffered on, though his physician had anxiously and faithfully plied his remedies one after another till his list of those of reputed value was exhausted. I can well believe this, for the father was a most intelligent man, with ample means; the mother

an anxious and loving woman, prepared to spare neither labor nor expense to bring health to her only son; but the skill of the physician had failed, the resources of specialists had proved useless, when in February, 1879, while he was in this pitiable condition she was informed by one of her friends who had heard of his case that I had several times used the snake-root tea with success. The father, knowing the plant, procured it. It was freely given, with marked advantage, and he was soon well. This very day, October 10, 1886, I have heard the history of the case from the lips of the parents; have heard this emphatic declaration of the mother: "I believe if he had had the snake-root tea in the beginning, he would have soon been well." He is now a strong, healthy young man. He and the boy of the preceding Case 3 are cousins, They began in a similar way; yet the one was treated by the infusion or decoction of the black snake-root at first, and was soon well; the other was given some of the twenty-nine remedies reported by Dr. Free; remedies, many of them—nearly all of them—in use before and at the beginning of this century, all of them often tried, sometimes with apparent success, but so often failing that authors were content to say, as matter of encouragement, "that in the failure of remedies to arrest it, it is devoid of danger, and may terminate spontaneously."

Coming still nearer to the present time, I will briefly notice three cases living within about two hundred yards of each other. I was invited, May 26th, by a young medical friend, to see with him a young girl with the following history: A school girl, who was 13 years old in June, 1885, and who passed naturally through her third menstrual period March 5th, was, during the next fortnight, to be examined for promotion, and of it she seemed to have much dread. She had but one more day to be questioned, the 26th of March, and when she rose in the morning she was morose, disregarded the directions of her mother, who became alarmed at the change in her behaviour, and on inquiring of her the cause of it, was told by her "that she felt bad and did not know what ailed her." A friend coming in detected the disease, and a physician was sent for. She went to bed; soon the choreic symptoms rapidly developed. She could not talk after that day, nor rise from her bed. What treatment was used is not known to me, but I do know that the medical treatment went on steadily under the almost daily supervision of the physician, the patient as steadily growing worse, until May 24th, when he informed the mother that "there is no hope." When two days later I saw her, she was indeed in a most suffering condition. It seemed dangerous to put any fluid into her mouth, so great was the difficulty of swallowing. She could not speak a word, her left side seemed paralytic. She had had almost no food for days, and there was a large bed-sore on her back, over the lower lumbar vertebra (produced by the continuous movement of her body), and also a contracted condition of the muscles of one side of the neck, which gave evident suffering when she attempted to swallow. Her face was fatuous in expression to a great degree. We arranged to give fluid ext. cimicifuga, prepared by Dr. Baker, of Norristown, made from roots gathered in proper season, dried and preserved properly, one teaspoonful *after* every meal and one at bed-time, if she could bear so much. The mother says that she saw a change for the better on the first day. Three days after our first visit we saw her again together, and the improvement was quite perceptible. She improved rapidly, so rapidly indeed as to astonish and greatly please my young friend, who for only a week had had exclusive charge of her. On the 3d of June, only seven days after she began to use the snake-root, she began to talk—imperfectly at first, of course, for she had not made an effort to do it for more than two months; in about ten days more was sitting up, and even walking about the room, and on the 25th of June walked a few hundred yards to her aunt's moving. When we think of the deplorable condition in which we found her on May 26th, and know that on the 25th of June she was out walking, and could talk as well as before she was sick, for all of which I have this story from the mouth of her mother and herself, we ought to regard the cimicifuga as being a valuable remedy, inasmuch as no other medicine was used, unless it was something at bed-time.

Case 5. On Sept. 14th was called to see a tall, gangling youth of 19, who, on May 3d, was entirely well of an attack of rheumatism which had confined him to bed for nearly three weeks. He lived about 300 yards from the case just narrated. I found him sitting in an arm-chair, but with numerous jerkings, contortions and grimaces, and exhibiting a peculiar wilfulness quite unnatural to him, which caused his aged grandparents to fear harm from him. He was at once put on the use of the cimicifuga, the fluid extract. He improved daily, and on the 18th his father, in order to comfort the old people, came from

Philadelphia and took him with him (he walking to the Spring Mill R. R. station, a quarter of a mile away), promising, too, to give the medicine as directed. On the 24th, the patient returned to Spring Mill by the train, greatly improved; again, a week afterwards, made a visit to Spring Mill, coming up from Philadelphia alone—apparently well save some imperfection in talking. Since then I have not heard of him save that he had ceased to take the medicine—not a very safe omission, even though he felt himself to be well.

While in attendance on the above case, I saw in the road a boy of about 11 years of age afflicted with chorea, and was told that he lived within 300 yards of the home of the boy of 19 whom I was visiting. Rather unusual to find in one small, scattered village, three cases of chorea affected at the same time. This pale little fellow attracted my attention as well as my pity, and, on inquiring of one who knew him, I was told that he had been afflicted for nearly if not quite three years; that a physician had attended him for a long time without effecting much, and that he had been subjected to other means of cure, and recently had been under the electrical treatment in Philadelphia.

Case 6. Allow me to speak of yet another case. In the spring of 1886 I was written to by a family in Norristown to visit a sick child. The object in sending for me was not to give it medicine, but to get him to the institution at Media for the care of imbecile children. When I was told the child's history, and was informed that "it had fits almost daily—sometimes two or more in a day" —I told the parents it was useless to attempt to get him there, as children subject to fits were not received. They desired me to see him, and he was brought into the room, they having previously given me his history as follows: "He will be eleven years old next July, the twelfth of eighteen children"—the mother now only 44 years old—"until he was four he was a smart boy. One day one of the girls took him out walking, in the afternoon, and returned towards evening carrying him, and he crying and paralyzed on the left side, yet he could talk. At 7½ p. m. he had another stroke, and fits for twenty-four hours, since which time he has never talked. For more than two years he had fits; was confined to bed, and could not walk; but gradually he grew stronger, ate heartily, and at the end of his two years' illness in bed he began to get about the floor, and finally to walk, and would then sometimes be a week without a fit." The month before I saw him he had three or four fits per week. When he came into the room to me he had hold of his mother's hand, and with his fingers thrust into a very large mouth, and it wide open, he jumped and capered along, jerking one leg, with the knee bent, as high as the thigh would allow it to come; he laughed, too, idiotically. The peculiar motion of one of his legs, his idiotic laugh, and capacious open mouth, impressed me with the idea that his case was possibly at first an acute severe chorea, that the fits were of the kind called "spells" by some persons, and not real epileptic fits. So greatly did this view of his case take hold of my mind, that I proposed to the mother to get a bottle of Dr. Baker's fluid ext. cimicifuga racemosa, and give him a teaspoonful after every meal; and also directed for him 20 grains bromide potassium every night at bedtime. The first week after he began to take the snake-root he had three fits; the next week two, after which he was three weeks with only one at the end of that time; and after that had none until the 22d of July, when he had one; then one in a week. Now, October 8th, he has not had any for four weeks. It was about April first when I first saw him, and the treatment was begun. According to this statement, he had during the month of April, after the medicine was begun, only six spells, or fits; then from about the first of May till July second —nearly two months—none; since then one about every week for three times, and since September 10th not one. But this is not all the improvement: his health is greatly better, he now walks quite well, with no jerking of his leg, tries to talk, knows what is said to him, when told to go sit down or to come to any one. Should he want a drink, will bring the empty cup for them to get it; if he needs food, will bring a knife. The bromide potassium was continued but a few days, for he soon began to sleep well, and when it was discontinued he slept as well as when using it. And here I ought to say that I have for many years used the cimicifuga for the purpose of enabling nervous people to sleep, and it has served them well. A member of our county society, who has often heard me speak of its value, when asked for his experience in relation to the effects of snake-root, gave me reports of its great value as a remedy in chorea, and also as a quieter of the disturbed nervous system, thus inducing sleep. At this time he has a lady who has had for several years a most painful and distressing affection, for the relief of which she for a long time took large doses of anodynes; but now whenever she becomes so nervous as to be

unable to sleep, a single half teaspoonful of Baker's fluid ext. cimicifuga will quiet the nervous restlessness and induce sleep. We have much talk about "nervous exhaustion," and the value of "strychnine and iron, and a little good whisky, as tonics to build up the system," and arsenic is the universal favorite in chorea; but I feel assured that all of them combined have not half the value of the infusion or fluid ext. of black snake-root, a plant that is accessible to every Pennsylvania doctor, as it grows on almost every wooded hillside in our State; and yet but few physicians are acquainted with it—cannot point it out, though it towers above nearly all the other plants of the forest.

Coming back from this digression to my poor Norristown boy, let me ask my readers if they do not see much similarity between this case and the one so suddenly taken, and so severely held until the time I saw it with my young friend; and might not this latter patient have gone on from year to year as the boy did, if not arrested by the cimicifuga? Again, might not the boy, who had been four or five years dosed with medicine and shocked by electricity, but was still strongly affected by chorea, have continued for years but for the control of his perturbed nervous system by this potent remedy, the snake-root, gathered by his father on the neighboring hill, and prepared for use by his mother? In every county in the State, I presume, it can be found; any mother can prepare and administer it; and were this done early in the cases of chorea which are found in every township in the land, physicians would not be mortified, and the inefficiency of our profession exhibited before the public by the appearance on our streets of young persons helpless in limbs and contorted in features by this disease of the nervous system.

THE RELATION OF CERTAIN FORMS OF DEFECTIVE VISION TO HEADACHE IN YOUTH.*

BY CHARLES F. SINCLAIR, M. D.,

Of Chicago, Ill.

He said that the headaches arising from defective vision are very numerous. They possess certain definite characteristics according to the degree and character of the ametropia. Thus, instead of the usual classification, the ophthalmologist might furnish a terminology of his own based upon the condition of the eye. The pain in these cases increases as the errors of refraction become more complicated. A woman had suffered with intensely painful headaches for fifteen years who was found to have mixed astigmatism, and here properly adjusted lenses effected a cure.

It is in childhood and youth especially that these different forms of ametropia manifest themselves in headache. Dr. W. H. Day, of London, however, in his work on the "Nature and Causes of Headache," in which he devotes a lengthy chapter to the headache of childhood and youth, does not mention ametropia as a possible cause.

Nevertheless the eye, among school children, is frequently the cause of all the head trouble. Among American children one form of ametropia is exceedingly common and very disastrous in its effects. It is difficult to detect. It may in certain cases simulate different forms of ametropia, and even normal vision. He referred to a case in which occurs a slight degree of astigmatism under one dioptric.

Maud W., a school-girl, 14 years old, had suffered with severe headache. On examination excellent vision was found, but minus lenses improved it and made it normal. After the use of homatropin, however, half a dioptric of hyperopic astigmatism was found, which was corrected and the headache cured.

Emily R., 15 years old, had suffered with constant headache for a year. On examination .50 D manifest hypermetropia was found, and only this corrected, as patient would not submit to the use of atropia. This patient returned in a few days, saying that her headaches were as bad as ever, when homatropin was used and a small degree of hypermetropic astigmatism was found. This being corrected, a cure of the headache was effected.

In another case there were constantly recurring attacks of vertigo and dizziness, together with severe unilateral headache caused by astigmatism, and which properly adjusted cylindrical lenses cured.

These are types of an exceedingly large number of cases where headache can be cured by a weak cylindrical lens. These cases are interesting not only because of their marked consequence, but because of their tendeucy, in certain cases, to exactly simulate other conditions; and they certainly suggest the advisability, in every case of severe headache, to examine the eye only when under the influence of atropia.

* Abstract of paper read before the Chicago Medical Society.

Medical Societies.

NEW YORK NEUROLOGICAL SOCIETY.

Stated meeting, October 5, 1886. The President, C. L. Dana, M. D., in the chair.

Case of Congenital Absence of the Faculty of Co-ordination.

Dr. G. M. Hammond presented a boy four years of age, brought to his clinic on account of inability to walk. He was born at full term; labor was natural; he appeared to be perfectly healthy at birth. But shortly afterward he became sick, and continued more or less ill for six months. The attending physician diagnosticated colic. Since recovery from this attack the patient had had no sickness. The special senses were normal; the patient understood as well as other children of his age. Perhaps he did not speak as plainly as he should, but two other children in the family, perfectly healthy, talked in the same manner. There was no history of syphilis. The patient was well formed; the muscles of the limbs were well developed for a child who did not walk; muscular reaction to both electric currents was normal; the reflexes were normal. The only apparent reason for his inability to walk was want of power to retain his equilibrium. He could crawl on his hands and knees perfectly well unless he attempted to go very fast, when he would fall, and he always fell toward the right. He could stand, holding to a chair, and walk pretty well if held upright. There was also incoördination in the upper extremities. He widened his base in standing. Dr. Hammond had not decided whether there was congenital absence of sensory tract in the cord or cerebellar disease.

Dr. Julius Rudisch had seen two similar cases, both in girls, one about eight years old and the other about thirteen. The first was seen some years ago, was under observation but a short time, and his recollection of the case was indistinct. But he was impressed with what he took to be muscular weakness; not simply ataxia, but weakness in the back. The child, if sustained, could walk well; if not sustained, it would fall, like the boy presented by Dr. Hammond. The older patient could walk, but in a peculiar ataxic way, and in the position of marked lordosis. The legs were well developed, and for that reason he thought the trouble was in the muscles of the back. The cases were not, in his opinion, congenital locomotor ataxia.

Dr. N. E. Brill thought such cases were not uncommon, especially among idiots. The gait of the boy presented reminded him of the swaying motion of a cat sent Dr. Spitzka by Prof. Wilder. Other actions than walking were natural. Rumf reported a similar case, and found a rudimentary cerebellum. Dr. Spitzka removed the cerebellum of this cat and found it natural. Dr. Brill thought we had to distinguish in these cases between locomotor ataxia and static ataxia. Dr. Hammond's case appeared to be one of static ataxia due to rudimentary cerebellum.

The President had found in his case books one in which a provisional diagnosis of infantile ataxia was recorded. The girl, about two years old, was well nourished, large, could not coördinate the hands or feet. In addition, there were some forced movements; the head would suddenly plunge forward.

Vesico-Genito-Post-Femoral Neuralgia and Neuritis.

Dr. Landon Carter Gray read a paper in which he described two cases, seen during the year, of a peculiar variety of neuralgia and neuritis that had not, so far as he had been able to ascertain, been hitherto described. The first patient was a man, aged 40, good general health, but marked lithæmic temperament, subject every summer to quasi- malarial attacks. Hitherto his neuralgia had been gastric, or intestinal. He escaped his usual attack this year, until in July the temperature fell in one night 48° F., and on the second day following, when getting out of bed, the patient felt a sharp, tingling pain through the buttocks, perineum, scrotum, tip of penis, and down the back of both thighs to somewhat above the knee. Some slight smarting was felt in urination. Toward the afternoon the pain began to lessen, but became much worse again following a Turkish and Russian bath. The cutaneous pains became violent, urination scalding, the bladder became paretic, the urine had to be forced into the urethra. For four days the temperature was from 100 in the morning to 102 or 103 in the afternoon, the neuralgic symptoms still existing.

The second case was that of a female, aged 35, seen in consultation with Dr. Burge, September 6th. During the past two years the patient had had a good deal of sciatica; otherwise had had good health. In December last she was suddenly attacked with sharp pain in the buttocks, perineum, labia, and down the back part of the thighs to the

knee. There was simultaneous retention of urine, requiring the catheter. Several weeks later Dr. Burge saw the patient, and found tactile anæsthesia of the buttock, perineum, labia, and the back part of the thighs to just above the knee. Dr. Gray saw the patient nine months after the onset of the trouble. She then had vesical anæsthesia, and voided urine without her knowledge. Over the area just mentioned, except the labia, which he was not allowed to examine, he found impairment of the tactile, temperature, and pain senses, but slightly less marked near the knee than above. There had never been any motor impairment.

These cases had a clinical interest, because a knowledge that such a neuralgia might occur would make us chary about diagnosticating a central affection, as we might well be inclined in the early stage, especially when there was vesical, motor, or sensory paralysis.

Dr. Rudisch asked whether an examination had been made for prostatitis, which caused symptoms in a degree like those described.

Dr. Gray said the area of distribution of the pain was not like that in prostatitis; besides, the second case occurred in a female.

Dr. W. H. Thomson referred to the case of a woman from the country, a locality said by her physician to be free from malaria. After a prolonged convalescence from an attack of pleurisy, she began to suffer severe pain in the anterior part of the left thigh, and from slight trouble with the bladder, the pains coming on certain days of the week, lasting one day and two nights. This continued five months, when she was free until the following fall. The medicine prescribed by Dr. Thomson had not prevented a return of the singular symptoms again the present fall. There was no indication of sciatica.

Discussion on the Uses of Hyoscyamine.

The President stated that there were two preparations of the drug, the crystalline and the amorphous. The former seemed to be similar in property to the opiates, while the latter seemed to have neurotic properties. He had heard that hyoscyamine was employed in the asylums for the insane in New York, but not very successfully, whereas in the asylums of Pennsylvania its success had been marked. He had employed hyoscyamine in paralysis agitans, in chorea, and in a few cases as a hypnotic, and it had been employed as a hypnotic to a considerable extent in his service at Bellevue Hospital. The number of cases of chorea in which he had used it was six; in three it was noted to have been of benefit, or caused very rapid or very marked improvement. One of the cases was marked, and had not yielded to other treatment. In three cases the results were very doubtful. He had employed it in four cases of paralysis agitans; in two he thought with unquestionable benefit, in two it seemed to produce no benefit. On the whole he thought that unless given at rather an early stage of paralysis agitans it did no good. The form employed in chorea and paralysis agitans was the crystalline, but he was not sure that the amorphous form would not be the better preparation in such cases. He thought we could get along perhaps as well without as with hyoscyamine.

Dr. B. Sachs' experience with hyoscyamine had not been very extensive, but he had employed it in a few cases of paralysis agitans, acute mania, and the insomnia accompanying the neurasthenic condition. He had employed only the crystalline form. In contradistinction to what the President had said, that it was best to give it in the early stage of paralysis agitans, he remembered one case in which every other therapeutic agent had been tried without success, when hyoscyamine was administered in about one-hundredth of a grain doses twice a day, with the effect of making the patient very much more comfortable, and of diminishing somewhat the annoying movements of the hand. In another chronic case it had been of no benefit. He had obtained no effect from the drug administered to allay the excitement of acute mania. It had also been disappointing in insomnia accompanying neurasthænia; it seemed to be of more value against insomnia from mental restlessness.

Dr. W. M. Leszynsky said that about eight years ago it was quite fashionable to use hyoscyamine in asylum practice, and he had employed it in chronic mania, acute mania, and epileptic forms of insanity. First he used the amorphous, and later sulphate of hyoscyamine. It was claimed that the latter form was easier absorbed, and produced its effects in smaller doses. The sulphate was also preferred for hypodermic use, in which manner he had employed it in one-sixtieth of a grain doses. To patients with recurring attacks of maniacal symptoms, the drug was given a few days before an expected attack and continued until the attack was aborted.

In a state of exhaustion he would regard hyoscyamine as a dangerous drug to administer, but where there was no objection to its use on that ground he had known it to pro-

duce sleep where chloral and morphine had failed. Given to patients subject to epileptiform convulsions before menstruation, it seemed to avert the attack. He had given it in small doses in two or three cases of chorea, and thought it produced some benefit.

Dr. L. C. Gray had been using hyoscyamine ever since it had been introduced to the profession, and he must say that for certain purposes there was no drug in the pharmacopœia that he could not better afford to dispense with. The most convenient form is in tablets, one one-hundredths of a grain. In some people hyoscyamine would produce seemingly serious retention of urine. It might also produce disastrous results if given to persons whose general strength was below par. In an old gentleman, with atheromatous arteries, hypertrophied and feeble heart, one-one-hundredth of a grain of hyoscyamine caused a condition of collapse. He knew of one patient suffering from melancholia who was sent to Greenwood by hyoscysmine. He had given it in two cases of chorea, one being an exceedingly violent case, the child finally dying in a convulsion. To that patient he could never give a second dose of hyoscyamine, because of the alarming prostration which a first dose would cause. In another case in which the child had to be held in bed, the drug proved an effective means of restraint, but the child was always found prostrated to a marked degree the next day. In paralysis agitans it had been very useful, and came to be with him a routine treatment. He thought the reason why it had been of more benefit in his practice was that he combined with it some stimulant or tonic to prevent its depressing effect. He gave with it good food, one or two grains of quinine a day, sometimes alcoholic stimulants. He had satisfied himself that it was the hyoscyamine in this treatment which had a restraining effect upon the movements in paralysis agitans.

But it was especially in cases of mental trouble where hyoscyamine was of great benefit. In insanity with hallucinatory symptoms, especially in the early stage before the patient could be taken to an asylum, hyoscyamine would do much toward restraining the patient, and it would seem, aided in cutting short the disease. He was very careful to give no more of the drug than was absolutely necessary, and he combined it with bromide of potassium, which increased its effect. He had never seen hypnotic effects from hyoscyamine.

Dr. W. H. Thomson said that his experience with hyoscyamine almost from the beginning rather prejudiced him against it. One of the first cases in which he employed it was that of a judge troubled with insomnia. The next day he was unable to hold court, had bladder symptons, etc. He found it useful in asthma with considerable dilatation of the right side of the heart, without bronchitis, but a congested state of the lungs. He had employed it in facial neuralgia, headaches, and various neurasthenic conditions, but had nothing definite to say about its effects. One patient with paralysis agitans was benefited by it, among many with whom it was a failure.

Dr. Kellogg had used hyoscyamine in cases of mental excitement, but it had not proven the sedative he had supposed it would. But it controlled muscular excitement. He had failed to get any hypnotic effect from it. He had not been favorably impressed with its after-effect in acute mania.

Dr. H. S. Hinkley had found it serviceable in allaying maniacal excitement. Dr. Waitzfelde, of the Pennsylvania Hospital for the Insane, had used hyoseyamide of bromine, and spoke very highly of it.

Dr. Richards had given five to seven drops of a one per cent. solution in several cases of insomnia, without effect.

PHILADELPHIA CLINICAL SOCIETY.

Stated meeting, September 24, 1886.

Dr. Henry Hartshorne in the chair.

Dr. Edward E. Montgomery exhibited a set of O'Dwyer's tubes for

Intubation of the Larynx,

with a description of the method commonly employed for their use. He had used the tubes in two cases, both being successful. In each child the relief of the dyspnœa was as great, and as instantaneous as after the performance of tracheotomy. The first child, æt. 6 years, had suffered for 24 hours from difficult respiration due to laryngeal diphtheria, and when seen was covered with perspiration due to the efforts to respire; the skin was cyanosed, and the sub-sternal region deeply depressed with each inspiration. The condition was such as the speaker usually regarded required tracheotomy, but the surroundings of the patient were not such as would render the result of that operation hopeful. Aided by Dr. West, the attending physician, one of O'Dwyer's tubes was inserted after a number of attempts, with immediate and profound relief. Considerable difficulty was experienced in feeding and in

the administration of medicine, owing largely, however, he believes, to the want of tact on the part of the attendants. After the administration of some stimulants in the afternoon, the tube was coughed up; the breathing again soon became exceedingly difficult, so that it became necessary a few hours later to re-insert the tube; it then remained two days, when it was again coughed up. Subsequent to this the convalescence was rapid and undisturbed.

A second case, æt. 3 years, seen in consultation with Dr. A. F. Chase, was in a more critical condition than the former. Here too the surroundings were very unpromising for tracheotomy. The tube was introduced without difficulty, its introduction being followed by great relief. No difficulty was experienced in feeding or in the administration of medicine; the tube remained in place four days, when it was coughed up. It was not necessary to re-insert it, the subsequent convalescence being unimpeded.

The results in these two cases with their unfavorable surroundings led Dr. Montgomery to have great confidence in the possibilities of this plan of treatment.

Dr. West gave a brief history of the case and its treatment before the introduction of the tube. He was called to see the child August 16. Found her with temperature 103° and great difficulty in respiration. He ordered potass. chlor. and tinct. ferri chlor. The next morning, as respiration was still more difficult, Dr. Montgomery saw the case and introduced the tube. Respiration became easy at once, and the child soon fell asleep. The same medicinal treatment was continued, with the addition of hydrarg. bichlor. The difficulty in the administration of food or medicine was its liability to excite a fit of coughing; and it was during one of these attacks that the tube was expelled. After the introduction of the tube there was the same difficulty; but by watching the child, and not allowing her to become excited, there was less trouble.

Dr. Mary E. Allen asked what prevented the tube from passing down into the trachea.

Dr. Amy S. Barton asked which operation was more readily performed—intubation of the larynx or tracheotomy?

Dr. Henry Hartshorne said that he thought many years ago intubation of the larynx should be used in preference to tracheotomy. A great advantage is that we can gain the consent of the parents and friends to this operation long before they will consent to tracheotomy.

Dr. McCollom said that five years ago he attempted to introduce a soft catheter into the trachea, but was not successful. He has used large doses of calomel in the treatment of diphtheria; in one case grs. x every hour until ℥ss had been taken. The temperature was reduced from 104° to 99° in twenty-four hours, and the patient was better in every way. He has also used the red iodide of mercury with excellent results.

Dr. L. Brewer Hall said that according to his observation patients were more liable to die from exhaustion, when suffering from croup or diphtheria.

Dr. Montgomery, in closing, said: "The reason patients, suffering from diphtheria and croup, are so apt to die from exhaustion, is on account of the degeneration of the blood from lack of oxygen.

"As Dr. Hartshorne remarks, one great advantage of intubation of the larynx over tracheotomy is the fact of gaining the parents' consent at an earlier date. The cause of so great a mortality after tracheotomy is that it is generally performed too late, and the blood has undergone these degenerative changes from want of oxygen. The patient will often seem to revive for a few hours or days, but generally succumbs finally."

The speaker said that in the first case he was at work nearly half an hour before he succeeded in introducing the tube, but in the second case he introduced it in about five minutes.

There is quite a shoulder on the tube, which rests on the larynx, and so prevents it from slipping too far. There is a bulging at the middle of the tube which prevents it from being coughed up, though when the membrane loosens the tube has more room, and is then readily expelled during an attack of coughing.

The difficulty in the administration of food may be obviated in children who are not nursing, by giving semi-solid food. In nursing children the milk is apt to flow into the tube, thence into the trachea. A nursing bottle has been invented with a long tube, which passes back into the œsophagus; there is a bulb attached, and by pressure on this the milk is forced into the stomach.

Dr. Edward K. Stone then gave verbal reports of two cases, as follows:

Case 1. Uterine bbro-cystoma mistaken for inversion. The patient, a married woman, aet. 30 years, sought relief from frequent, almost constant metrorrhagia. The hemorrhage had continued ever since the birth of her only child, thirteen months before. Labor was comparatively easy, and was superintended by a midwife. The patient was

rather stout, but extremely pale and bloodless. Examination revealed a smooth, rounded, elastic mass in the vagina, and connected with the interior of the uterus by a pedicle about the thickness of a man's finger. The tumor was about three inches in its longest (lateral) diameter. The cervix uteri admitted the finger for a short distance, and this could be plainly felt through the abdominal walls, the body of the uterus appearing to be absent. There was a distinct depression in the uterus above the cervix. The sound was *not thoroughly* used at the time, so the depth of the uterus was not ascertained. Some efforts were made to reduce the *supposed* inverted uterus, when the body was found retroflexed and bound down by adhesions. The tumor was attached just within the os interium, and its weight had slightly inverted the uterine wall. The mass was readily removed without accident with the ecraseur.

Case 2. Patient aged thirty-five years; married; has had two natural deliveries at term, and several abortions, produced by the passage of instruments. Has had menorrhagia and metrorrhagia for two years. The cervix was dilated, and examination revealed a tumor about the size of a small hen's egg, sessile and attached to the right and posterior wall of the uterine cavity. An operation for its removal was attempted, but was abandoned, as the mass involved the uterine tissue so deeply. The mucous membrane was freely dissected from the surface, and the tumor enucleated as far as possible. Ergot was afterwards administered, and the tumor was forced out beyond the cervix.

Severe septicæmia, due to sloughing of the mucous membrane, ensued, which prevented further operation; and the mass, which had formed a new attachment to the interior of the cervix, gradually increased in size until a mere thickening of the cervix on the right side is all that remains of the disease.

Hemorrhage has not recurred, the periods being normal in time and quantity, and the uterus of normal size.

Ovariotomy for Dermoid Tumor in a Child Thirty Months Old.

Dr. J. F. Hooks thus writes in the *American Journal of Obstetrics:*

Ada Hurst, female, aged thirty months, was brought to this place from Delta county by her parents, June 25, 1886. Two physicians of Delta county had been treating the case as one of ascites for several months. Dr. E. W. Rush and the writer were requested to examine the case, with the view of making a diagnosis.

In company with Dr. Bramlette, of this place, we made a careful examination under anæsthesia, which resulted in a concurrence of opinion as to the existence of an abdominal tumor, and we were inclined to believe it ovarian, notwithstanding the age of the child.

The child was fairly developed for her age, and had always enjoyed good health. The abdomen was enormously enlarged, measuring twenty-nine inches in circumference at the umbilicus; above the umbilicus, as high as the ensiform cartilage, it was much larger.

The result of our conference as to the character of the tumor, the necessity of operative interference to save the life of the child, together with the dangers attending so formidable an operation upon a child of her age, were fully laid before the parents, who were advised to confer with their physicians, and determine for themselves what course they would pursue in the matter.

The child was taken home, but on the 2d of July they returned, the parents having become fully convinced that the child would live but a short while unless some relief could be rendered. They had, therefore, fully made up their minds to have an operation performed. On the morning of the 3d of July—Dr. Fort having been requested to see the case with us—the patient was again chloroformed, and a second thorough examination made, with the view of removing

any doubts, should they exist, from the minds of the consulting physicians as to the nature of the tumor or the propriety of an immediate operation for its removal. The result of this second and more thorough examination was confirmatory of the diagnosis previously made, namely, that the tumor was ovarian, and had its origin in the left ovary. Treatment was instituted to put the child in the best possible condition to undergo the operation, which it was decided should be undertaken on the morning of July 6.

I would state just here that the parents of this child first observed a slight enlargement of the abdomen about twelve months ago, but for the last six months the increase of growth had been very rapid. Even the few days which lntervened between the first and last examinations showed a perceptible increase in the distention, and a corresponding increase in difficulty of breathing. That the child could survive but a short time in its present condition was apparent to all who saw it.

On the morning of July 6, the patient being anesthetized by Dr. Bedford, the writer, assisted by Drs. Rush, Bramlette, Fort, and other medical men of this city, under every antiseptic precaution, proceeded to make an abdominal incision extending from just below the umbilicus to near the symphysis pubis, an incision some three or three and a half inches in length. This incision was made short, for exploration, and with the intention of evacuating the sac, and drawing it through the incision in the event it proved to be a unilocular cyst. Immediately upon opening the peritoneal cavity, quite a large pellucid sac with extremely thin walls rushed out and ruptured. This sac or cyst sprang from the larger tumor on its lower anterior surface, above the pedicle. The main tumor was large, firm, and resisting, and completely adherent all over its anterior surface. I endeavored to evacuate the main tumor with trocar, but failed, as its contents were too dense, viscid, and semi-solid to pass out through the instrument. I incised the tumor and endeavored to break it up, but failed. The incision was then enlarged, and the adhesions to the parietal walls and omentum were broken down with the hand; the entire lower part of the tumor, that is extending far down on each side from its anterior surface, was firmly adherent to the omentum. It was not until the incision had been extended to near the insertion of the diaphragm that the adhesions could all be broken up and the tumor extracted. When lifted from its bed, it was found to spring from the left ovary by a short, thick pedicle, which was at once transfixed with a needle, armed with stout iron-dyed silk ligature, doubled: ligature was then cut and tied both ways, pedicle cut, and tumor removed.

There was no hemorrhage from stump of pedicle, which was mummified with a weak solution of persulph. iron, and returned to abdominal cavity; the ligatures attached to the same being brought out at the lower end of the abdominal incision.

There was considerable blood oozing from the adherent surfaces, and several catgut ligatures had to be applied to bleeding vessels in the omentum, all of which created considerable delay in closing the wound.

In closing the abdominal wound, the peritoneal edges were first brought together by non-interrupted catgut suture, silk being used for closing. The external wound was supported by one or more deep-seated wire sutures entering near peritoneal edge and coming out some half inch from the margin of abdominal incision. A drainage tube was placed at the lowest angle of the wound, which was dressed strictly antiseptically. The little patient reacted promptly from the effects of the anæsthetic, and seemed bright and cheerful. A hypodermic injection of morphia was given, and the patient rested well for some two hours or more. In a short time after the child was aroused from sleep or the quietude produced by the morphia, she became restless, and the temperature soon ran up to 102°. Thirst, which was great, was allayed by pellets of ice.

At 7 p. m., $\frac{1}{15}$ gr. of morphia was given hypodermically, which produced quietude for a few hours. She still suffered greatly from thirst; temperature continued to rise, until from 12 to 1 o'clock it registered 105°. From 1 to 7 a. m. on the 7th there was a slight lowering of temperature, no diminution, however, in the excessive thirst, and great restlessness. At 10 o'clock on the morning of the 7th, the temperature having again gone to 105°, I raised the dressing to see that all was right with the wound. There had been but little drainage from the tube, and everything was sweet and clean. I injected a few ounces of weak solution of carbolic acid and muriate of soda through the drainage tube, which returned with only a slight stain of bloody serum in the first few drachms. There was no unpleasant odor of the wound or of the returned fluid.

The little patient, however, grew more restless, became unconscious, and death closed the scene at about 2 p. m. the day after the

operation, the patient having survived the operation about twenty-four hours.

The tumor, after removing all we could through the canula, the trocar having been plunged into every cyst which it was thought would drain, with the view of reducing the bulk of the tumor as much as possible, weighed nine and a half pounds, and was composed of numerous cysts filled with a jelly-like fluid, some cheesy; much of the tumor was comparatively solid, being filled with a white, thick, cheesy matter, interspersed all through with hair and bony deposits.

I attribute the fatal termination of the case to the extensive adhesions formed, and the magnitude of the operation in a child of such tender years.

A Case of Chronic Cirrhotic Kidney.

Dr. H. McHatton thus writes in the *Atlanta Med. and Surg. Jour.* for October:

Last night, at 9 o'clock, I was called to see Mr. C., American, aged 40, of good family and personal history. I found him suffering from nausea—he had been vomiting more or less all day. Pulse 70, hard and full, temperature normal. Left ventricle slightly enlarged, muscular element of first sound decidedly accentuated. Some dizziness. Said he often had specks before his eyes, and that after being on his feet all day they were slightly swollen. Kidneys acting well. Had noticed nothing unusual about his urine. These attacks came on about once a month, and he has a feeling of general malaise between times. He has seen three physicians; two of them examined his urine and said there was nothing the matter with it. All gave him our favorite diagnosis, which is even more fashionable than our Northern brother's malaria, namely biliousness. I gave him a mixture of bismuth and spt. ammon. aromat. to quiet his stomach, and took a specimen of urine for analysis, which gave the following result: Color, pale and clear; sediment, very slight: odor, normal; reaction, neutral; specific gravity, 1012; heat and nitric acid test, negative; Heller's test gave a very faint, cloudy line; hyaline and granular casts, both large and small, abundant.

From this examination and the history, I made a diagnosis of chronic cirrhotic kidney. On my visit, at 11 a. m. to-day, I found him in uræmic coma, from which he could be aroused with difficulty, and when aroused was incoherent. He had fallen out of bed during the morning, injuring his face and head, besides biting his tongue badly, of which fact he was not conscious. I gave him the following prescription:

℞. Hyd. chlo. mit.
Soda bicarb., āā grs. x.
Chart No. 1.
S.—One dose.

℞. Kali acet., ℥ss.
Inf. digital., ℥iii.
M. Sig.—Teaspoonful every two hours.

On my visit at seven to-night I found him in perfect possession of his faculties, bowels and kidneys acting freely; in fact, he is as well as usual, and barring intercurrent affections, will continue so until he gets another accumulation of urea.

This case is a true type of the most insidious and probably the most frequent of all the kidney diseases that we group for convenience under the name of chronic Bright's. It is far more common than we suppose, this being the third of the kind that I have seen lately. It is in this class of cases that we get the sudden and often fatal manifestations of uræmia with little or no premonition. They do not give the train of symptoms that we are in the habit of associating with Bright's.

The urine in gross appearance is usually normal; the quantity is often in excess, but the specific gravity is usually low. Albumen is rarely abundant, and often entirely absent. Dropsies are as a rule absent, and if present are not of much importance. In fact, there is rarely any symptom that will invite our attention to the kidneys if we are not especially on our guard.

Our patient usually presents himself complaining of a general sense of malaise, or with one of the complications of his disease. A general sense of failing health, with hypertrophy of the left ventricle without valvular lesions, and urine of low specific gravity, in a patient of middle age, should always induce us to make careful and repeated examinations of the urine.

In regard to the treatment of these cases, the damage to the organ is done and we cannot reproduce the destroyed part; but even if the secreting substance is destroyed to the extent of the bulk of one kidney, the condition is not incompatible with life, or even a fair state of health; by judicious management we can often guide these cases through years of usefulness.

There is of course no special medication for the disease proper, and our dependence is on hygience and tonics, of which, in view of the existing state of anæmia, iron should be the principal. If our patient can be induced to use it, it is best to furnish him with

a urinometer, and get him to take the specific gravity and quantity of his urine every few days. By taking these two factors (either one being of absolutely no value alone), a glance at the table in most of the works on urinary analysis will show us if he is passing sufficient urea; as long as he is doing so, let your diuretics severely alone, as they are at that time not only useless, but even contra-indicated—for by stimulating the kidneys when there is no call for it, we will be less liable to get a response to our medication when it is of vital importance. The same line of treatment holds good in respect to the heart; so long as the hypertrophy has not reached its limit, it is bad judgment to use cardiac stimulants (excepting in cases of urgent necessity during an accumulation of urea), for eventually, should the patient live, this condition of hypertrophy will be followed by dilatation, and then we will have urgent need of our cardiac stimulants.

Our Therapeutical Inheritance.

Dr. Frank W. Vance, of Memphis, Tenn., thus writes in the *Weekly Med. Review:*

We are prone to look to antiquity for wisdom, and to regard the crude ideas of our predecessors as embodiments of truth gathered by ages of experience. The ages have bequeathed to us their truths of experience, and also their dogmas of false theory and undeveloped knowledge, which bearing the stamp of authority have commanded respect wholly unentitled to. False ideas have brought forth dogma, while dogma has moulded practice to fit its forms; and erroneous practice is bequeathed to us, a seeming product of human experience that is above question.

It is only at a late day that anatomy and physiology, with dissections and vivisections, have brought to light the mysterious architecture and function of the human body. Antiquity forbade dissection, consequently physiology was impossible, and in place of our modern science, a nescience was established, based on vague metaphysical principles and formulæ, that was carried into the domain of pathology. A false physiology and pathology could not but originate a false therapeutic system, but strange to say, although we have abandoned the literal interpretation of the nomenclature of the fathers of medicine, the great majority have not given up their therapeutics. When philosophy sounded the death-knell to the paganism of the Greco-Roman world, there were yet many who clung to the superstitions of their fathers. Literal paganism was an impossibility, but by amalgamation with the science of the age, a philosophic paganism was developed, the literal expression of which symbolized truths approached to by preceding antiquity, but left for the succeeding age to elaborate into scientific perfection.

Even so have the medical superstitions of our predecessors been looked upon as inklings into physiological and pathological truths, and associated with modern physiological, pathological and therapeutical endeavor.

If the fathers of medicine had stopped after elaboration of their false physiology and pathology, all would have been well; but they undertook to build thereon a false therapeutic system that has been the bane, and still is, even at this date, of suffering humanity. The power of modern physiological investigation has broken down the nescience of the past, but where is the power that can destroy the modes of therapeutical procedure based on demolished theories? For these modes are the inheritance of the past, and slovenliness of judgment, on which authority has set its seal—except in the case of a physiological fact brought direct before the mind contradicting a former theory—is by no means an easy matter to overcome. And then there is deliberate falsification of clinical facts by many, whose respect and reverence for authority antagonizes any independence that they ought to and should possess. Excepting bleeding, that is to a great extent abandoned, purgation, vomiting and counter-irritation are still persisted in, although correct clinical report has failed to show that either has ever resulted in anything but real harm. I allude to purgation and vomiting in the sense of means to treat disease, based on ancient theories of morbific humors and revulsion and fluxion, and not as any endeavor to get rid of a poison intentionally or accidentally received into the system. In regard to counter-irritation, it was practiced long before anatomy, physiology and pathology were dreamed of, and the same method of procedure was brought about, not by experimental good, but as the natural offshoot of metaphysical theories of disease. To follow out the evolution of medical dogma from the earliest times is foreign to my purpose, but by consultation of the oldest authorities down to John Hunter, and even to the orthodox therapeutics of the present day, we can witness the development of erroneous ideas and assertative dogmatism, whose only claim is that the judgment of preceding authority is superior to ever-advancing scientific achievement, that completely demolishes one by one the ideas of our boasted inheritance of the past.

Case of Spina Bifida Successfully Treated by Operation.

Dr. John Kellock Barton thus writes in the *Lancet:*

Inasmuch as the treatment of spina bifida is still unsettled, any case in which a successful operation has been performed is worthy of record. So, very briefly, I will state the particulars of the following case which has been lately under my care in the Adelaide Hospital:

On July 9th, Susan H., an infant two weeks old, was brought to the hospital by her mother, who had been attended in her confinement by Mr. Hamilton, a pupil of the Adelaide. He had noticed at the time of birth a tumor in the lumbar region, about the size of a small walnut, of a dark purple-red color. This tumor steadily increased in size, and at the time I made my first examination was the size of a small egg, or might more accurately be likened to the half of a small orange, the convex part projecting, the flat or cut surface of the orange attached to the lumbar spine. The surface of this tumor was occupied by a greyish sloughy ulceration, while the sides were of a deep purplish-red color. Fluctuation was very obscure, but pressure certainly diminished the bulk of the tumor, which regained its original size quickly when the pressure was removed. The nature of the tumor, so far as that it was a spina bifida, was pretty clear; but to make this more certain I thrust a fine hypodermic needle into it, and drew out a few drops of a perfectly colorless serum. The question of its being a spina bifida was now established, but the further and more difficult one of whether the spinal cord formed any portion of its contents, remained doubtful. The fact that no paralysis existed, either of the sphincters or lower limbs, induced me to believe that this was a meningocele, and not a myelocele; but the facts of its low position and of its purple and ulcerated surface are held by authors as leading to an opposite conclusion; and the result proves that the freedom from paralysis is of more diagnostic value in deciding this important point than is either the situatiou or the character of the tumor.

Next day, I performed the following operation, the infant being under the influence of chloroform: I cut an elliptic piece out of the centre of the tumor, thus removing all the sloughy central portion; the wall was thick, internally smooth and white, and with numerous small nerves passing into the portion removed, which were, of course, cut across. Very little time was lost in stopping all bleeding, which was insignificant, and then drawing together the thick purple flaps left on either side by a double row of sutures. Careful antiseptic precautions were observed, and the dressing consisted, first of all, of a dusting with iodoform, then a covering of corrosive gauze (1 in 400), secured well at its edges and round the body with an antiseptic gauze bandage. There was no elevation of temperature, and union was complete and firm in a week. No signs of any disturbance of the nervous system followed.

In ten days the infant was discharged cured. I questioned the mother as to any loss of power in the limbs, of which the child has free use. The situation of the tumor is now occupied by a puckered purple oblong swelling, about one-sixth of the size of the tumor which I operated upon, and I have no doubt further contraction will go steadily on for some time.

P. S.—Since this report was written, I have received information of the death of the child in a fit of convulsions. No doubt the union of the operation-wound was complete, but the convulsive attack came on too soon after the operation for us to dissociate the one from the other.

Herpes Preputialis.

Dr. James C. Pearson thus writes in the *Indiana Med. Jour.:*

Mr. B., aged 58 years, contracted gonorrhœa, which appeared on the sixth day of exposure. He had a copious discharge of thick, puriform matter from the urethra, with its usual attendants—ardor urinæ, painful erections, chordee, and prepuce contracted back of the corona glandis. On examination I found the mucous surface thickly set with minute vesicles behind the corona glandis, forming a complete cincture around it. He stated that he had treatment for his urethritis and thought he was well, and now he presents a case of blenorrhœa chronica of Dr. Good. The inguinal glands of both the right and left sides were enlarged. I was at a loss to decide whether his was a case of follicular chancre or syphilitic ulceration of the prepuce; but as the vesicular eruption in its appearance was simultaneous with the urethritis, I was willing to decide that follicular chancres and syphilitic preputial ulceration did not so originate.

I prescribed:

℞. Liquor plumbi, ℥ iss.
Aquæ distill., ℥ vj.
M. And apply on lint to vesicles four or five times a day; and,

Take one powder of the following three times a day:

℞. Pulv. cubebs,
Sulph. alumina and potassa, āā ʒj.
M. Ft. chart No. xii.

On the fourth day he reported vesicles disappearing, urethral discharge less. I gave him twenty-four powders, and ordered him to report in eight days.

2d report: Discharge from urethra was better; herpetic vesicles had appeared on the skin of the prepuce.

I ordered him:

℞. Acidum hydrocyanicum, ʒij.
Spiritus rectificati, ʒij.
Aqua distillatæ, ℥iv.
M. And apply on lint to vesicles.

Liquor arsenici hydrargyri iodidi ♏v–♏xxx three times per day for ten days, then report at my office.

3d report: Vesicles had left the skin of the prepuce, and were now affecting the urethra, causing a feeling of fulness in and about the prostate, so that in urinating the sphincters in contracting felt obstructed as if closing upon a ball.

I ordered him to omit the Donovan's mixture and take:

℞. Ferri arsenitis, gr. iv.
Ext. gentianæ, ℈ij.
Pulveris glycyrrhizæ, ℈iv.
M. Ft. pills x. One pill after meals, night and morning.

Tinct. ferri chloridi ♏xx at 10 a. m. and 2 p. m. each day.

℞. Liquor sodæ chlorinatæ, ʒiij.
Aqua fontana. ℥x.
M. And use as an injection three or four times a day.

4th report: Urethra and prostate better. Vesicles cluster on the under surface of the prepuce and around the corona glandis. With a mixed feeling of disappointment and desperation, I prescribed permanganate of potassium in doses of gr. ij in water three times a day.

℞. Sodæ murias,
Soda bicarbonas, āā ʒj.
Aqua distill., ℥viij.
M. Inject in urethra three times a day.

To my great astonishment, now that six months have passed, he has experienced no further trouble *causa sine qua non* from this intractable form of disease.

Neuropathic Affections of the Joints.

At the fifteenth Congress of the German Society of Surgery, Professor Czerny, of Heidelberg, pointed out the frequent occurrence of spontaneous fracture in tabetic patients, and considered the question whether, since abnormal fragility of bone decidedly occurs with several other diseases of the nervous system besides tabes, arthropathies analogous to the tabetic are not also to be met with in those neuroses. Six cases were reported of joint-disease, in connection with diverse affections of the central nervous system. There can be no doubt, according to Czerny, that neuropathic subjects are, like—and probably to a higher degree than—other men, predisposed to all possible forms of arthritis. To any objection that the reported cases refer simply to ordinary instances of different forms of arthritis in neuropathic subjects, Czerny would reply that the course of the arthritis in every case is so considerably modified and influenced by the disorder of innervation, that it is very necessary, from a practical point of view, to separate these from ordinary forms of arthritis. Great stress is laid, in this communication, on increased vulnerability of the tissues in neuropathic subjects. This certainly is not so striking with chronic lesions as after crushing injury of the spinal cord, but still decubitus and acute inflammation of the urinary system play a considerable part in the final stage of tabes. As an instance of an affection not dangerous under other conditions proving fatal when associated with tabes, Czerny quotes the case of a tabetic subject who had contracted gonorrhœa, and died after an interval of four weeks from pyelonephritis, cystitis, and purulent pericarditis. Notwithstanding this vulnerability of the tissues, fractures unite and operation-wounds heal very favorably in tabetic subjects. The chief diagnostic signs of neuropathic joint-affections are, it is held, the rapidly destructive course in acute cases, and, in chronic cases, the analgesia, excessive exudation, and extensive destruction of the elements of the joint. In cases of sprain or fracture, especially when the latter injury is due to slight violence—should there be analgesia, it is necessary, Czerny states, to make a careful investigation into the condition of the nervous system. The direct causes of the joint-affection in Czerny's six cases were injury in two, inflammation without any injury in one, and certain trophic conditions of the hand (muscular atrophy, analgesia, contraction of fingers) in the remaining three. These trophic conditions seemed to have been the result of frost-bite. In two cases, well-marked disease of the spinal cord was made out after death; one patient was tabetic. In the remaining patients, who were living at the date

of this paper, disease of the cord was indicated by muscular atrophy with contracture of the fore-arm, and analgesia. With regard to treatment, Czerny advocates rest and confinement of the affected limb in splints, with a view of obtaining ankylosis. In cases in which there is advanced destruction, or when suppuration has been established, and threatens mischief, it will be necessary to decide between arthrotomy, resection, and amputation.

On a Case of Abdominal Pregnancy; Termination by Ulceration into Rectum; Recovery.

Dr. Ralph Browne thus writes in the *Lancet:*

E. J., aged forty. Has had ten children, the youngest being five years old. Has not had any miscarriages, and gives no history of previous disorders in the organs of gestation. She had last menstruated in November, 1884 (seventeen months previously). She believes herself to have been in her usual good health, and does not remember to have had any fright about that time. In the course of a month or so she began to suffer from metrorrhagia, which continued, and led her to seek advice.

On examination, a tumor was found upon the left side of the abdomen. From its position and feeling, it was diagnosed as ovarian, and it was also suggested to the patient that she was pregnant. The metrorrhagia continued more or less, until in September, 1885, or at what would be about the full period of pregnancy, a pseudo-labor took place, and an effort at lactation appeared in the breasts. About this time the patient began to notice that the tumor seemed smaller, but complained of loss of appetite, general ill-health, and pain and irregularity in the action of the bowels. This state of things continued until April last, or seven months after the pseudo-labor, when she was taken with violent forcing pains in the body and lower bowel, and offensive diarrhœa, in the course of which some fœtal bones were passed. Examination of the rectum disclosed the presence of the remainder of the fœtus. A hand was introduced into the bowel, the fœtal head crushed as far as possible with the fingers, and its fragments and other bones removed. The diarrhœa, and the occasional passage of a remaining bone, continued for a few days, gradually became less offensive, and then ceased. Within a fortnight the patient was able to leave her bed, and has since made an uninterrupted recovery.

From the frontal bones removed entire, each measuring an inch and a half by an inch and three-quarters, and from the other cranial bones fitted together, the bi-parietal diameter was computed to be three inches. All the bones had the normal amount of ossification of a full-time fœtus.

Points of interest in this case are: 1. The difficulty of diagnosis, though, looking back now, nothing can be clearer than the sequence of events. 2. The maturity and perfect formation at which the fœtus arrived. 3. The means taken by nature to remedy her error, and which resulted in perfect recovery.

Rupture of the Gravid Uterus.

Helène S., aged 48, pregnant for the seventeenth time, was admitted into the Kochanow Hospital on December 27, 1884. She was cachectic and suffered from daily pyrexial attacks. The last menstrual period was September, 1883, and she first felt fœtal movements in January, 1884. In May she ran a considerable distance with bare feet, and this exploit was followed by shiverings and fever, abdominal pain, and slight metrorrhagia; the fœtal movements ceased two months before the calculated termination of pregnancy. A week later a redness was noticed in the neighborhood of the umbilicus, which subsequently broke and gave exit to a bone. The opening gradually increased in size, exposing other bones and the softened tissues of the decomposed fœtus. A fortnight later fæcal matter escaped by the opening, which continued to increase in size. In the month of September two small bones escaped *per anum.* The umbilico-uterine wound was now enlarged by several radiating incisions, and the fœtal remains were extracted. The uterus was firmly adherent to the abdominal walls in such a way that nothing could escape into the peritoneal cavity. The os uteri allowed the passage of a finger, and a probe introduced through the cervix came out at the umbilical opening. In the cavity of the uterus there were two openings from which fæcal matter escaped, the contents of the intestines thus having exit through the anus *via* the uterus and vagina, and through the abdominal opening. After removing the fœtus, careful irrigation was carried out for some weeks, the uterus being plugged to prevent escape of fæces ln that direction; but although the general health of the patient improved from day to day, the fistulæ continued patent. The patient ultimately decided to return home. She was seen not long since; the abdominal wound, much lessened in size, only gave exit

to a liquid devoid of fæcal odor; the bowels were regular, and two months ago she noticed what she took to be her period, lasting one day.

The Local Treatment of Pseudo-membranous Croup; Intubation of the Larynx.

Dr. J. Lewis Smith, in an article in the October number of the *American Journal of the Medical Sciences,* expresses his belief that intubation is destined to be employed more generally than tracheotomy in the treatment of pseudo-membranous croup. He maintains that in all cases in which the obstruction is limited to the larynx and trachea, intubation relieves the dyspnœa as quickly, effectually, and permanently as does tracheotomy. It gives, in most instances, complete relief for a time. If the respiration subsequently become embarrassed, and no benefit occur from cleaning the tube, tracheotomy may be required. Intubation may properly precede tracheotomy in most cases.

Not a few parents, in the middle and lower classes, allow their children to die rather than consent to this operation. On the other hand, few parents will object to intubation, and when they see the relief which it produces they will probably consent more readily to tracheotomy if the dyspnœa should return. If only one of these operations be performed, statistics thus far show nearly as good a result from intubation as from tracheotomy.

Now, that diphtheria has become so common, the physician should be provided with instruments for intubation whenever diphtheria appears in his locality. Alkaline and trypsin inhalations, properly and almost constantly used, and intubation performed early, when the patient begins to suffer from dyspnœa, would probably prevent the necessity of tracheotomy in a large proportion of instances. But if such treatment do not fully relieve the dyspnœa, it will, in most instances, so diminish it and retard the progress of croup, that the physician, remote from help and unfavorably situated for the performance of tracheotomy, will have ample time to prepare for this operation. Intubation may prevent the need of tracheotomy, but if not, it presents no hindrance to it.

Urinary Difficulties Occurring in Boys.

In the *Lancet,* August, 1886, p. 339, Mr. Wm. Thomas publishes an article upon the urinary troubles of children. Amongst the cases recorded one is especially interesting. A boy, aged, 11, was admitted into the infirmary, having about twenty-four hours previously fallen with his perinæum across a rail. A catheter could not be passed. When seen by the author the scrotum was much swollen and greatly ecchymosed, together with the perinæum. Under chloroform free incisions were made into the scrotum on each side, but no urine was obtained. A catheter was introduced into the urethra, but did not enter the bladder; a cut was then made on to the end of the catheter, and it was found to be in a large cavity which was filled by coagulated blood and some urine. The bladder was next aspirated above the pubes, twenty-three ounces of slightly turbid urine being withdrawn. The boy was then put to bed to watch events. Next day chloroform was again administered, and while in the lithotomy position an incision was made in the middle line down to the bulb of the urethra, which was found to be torn across just behind the bulb, the posterior part being quite retracted and separated for about two inches. A catheter was easily passed, drawing off some urine. A lithotomy staff was next passed along the whole extent of the urethra into the bladder, and the separated parts brought together and stitched with three silver-wire sutures, passed completely through the walls of the urethra, and each tied outside in a reef knot. With the staff still in the bladder, the membranous part of the urethra was opened by an incision to allow the urine to escape, and to keep the stitched part at rest. A drainage-tube was then passed through this incision into the bladder. A fortnight later the perineal wound was closed, and all urine came through the urethra. The boy did very well, and no sign of stricture remained.

Tonsillitis in Adolescents.

Dr. C. Haig-Brown has published his M. D. thesis upon a very common affection, of which, in his capacity as medical officer at Charterhouse School, London, he has necessarily had considerable experience. The monograph contains much matter of interest—such as, for example, the fact that 105 out of 127 consecutive cases occurred in lads between the ages of fourteen and seventeen; the undoubted association of some cases with the rheumatic diathesis, or more immediately as a precursor of an attack of acute rheumatism; the humidity of the atmosphere as favoring tonsillitis, and the equally notorious influence of defective drainage. Dr. Haig-Brown is convinced of the contagiousness of tonsillitis, and sketches two epidemics that

occurred in his practice, from the study of which he concludes that the contagium is most virulent at the commencement of the disease, at a stage when it is often overlooked. Amongst complications he discusses very fully the development of cardiac murmurs, which were met with in 9.4 per cent. of cases where there was no previous history of rheumatism. In eight cases out of 345 the evidence was conclusive in favor of endocarditis, for they terminated in chronic valvular disease, and in three there was distinct evidence of pericarditis. It would have been valuable to have had statistics upon the occurrence of albuminuria, but this is a point which is not specially touched upon. As to treatment, the opinion is expressed that, like acute pneumonia and many specific fevers, tonsillitis runs its course uninfluenced by drugs, and this applies not only to guaiacum, aconite, and chlorate of potash, but also to salicine and the salicylates, with the reservation that the latter may possibly in some cases avert an attack of rheumatic fever.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Among recent reprints of interest, we may mention one on "Contagious Eye Disease" by Dr. Joseph H. Andrews, of New York city; on "Methods in Medical Study," by Dr. Charles H. May, of New York; on "Two Rare Cases of Abdominal Injury," by Dr. J. A. Stucky, of Lexington, Ky.; on "The Removal of Foreign Bodies from the Larynx," by Dr. Max Thorner, of Cincinnati; on "Recent Experiments in Clinical Surgery," by Dr. Donald MacLean, of Detroit; and on "Extra-uterine Pregnancy," by Dr. M. O'Hara, of Philadelphia.

——On the subject of the illumination of the cavities of the body by the electric light, we have before us a paper by Dr. J. A. Andrews, of New York city, discussing the effect of strong light on the eye; and one by Dr. J. M. Roberts, also of New York, presenting a novel plan for the illumination of bones by electric lamps of half-candle power.

BOOK NOTICES.

A Manual of Animal Vaccination, Preceded by Considerations on Vaccination in General. By Dr. E. Warlomont. Translated and edited by Arthur J. Harries, M. D., etc. Small 8vo. Pp. 152. Philadelphia, J. Wyeth & Brother, 1886.

Dr. Warlomont, director of the Belgian State Vaccinal Institute, has long been known as one of the most eminent authorities on bovine vaccinal preparations. In this small volume he has condensed the results of his extended observation and studies, and presents them with force and lucidity. Any one who continues to doubt the superiority of the lymph derived from the heifer to that which has passed through a number of human systems, would, we think, be convinced of his error by perusing these pages. The author speaks both of the theory of vaccination and of those methods and precautions which are advisable in order to secure for it the greatest efficacy.

The work is published by Messrs. John Wyeth & Brother, the well-known firm of manufacturing pharmacists, who themselves conduct one of the most perfectly-organized vaccine propagating establishments in this country. The volume can be had on application to them, and we recommend our readers to drop them a line and secure a copy.

How We Treat Wounds To-day. By Robt. T. Morris, M. D., etc. Second edition. 12 mo. Pp. 165. New York, G. P. Putnam's Sons, 1886.

The author tells us that the first edition of this little manual met with an "enthusiastic reception." This we attribute as much to its manner as to its matter. Dr. Morris has a style all his own in medical literature, and impresses what he says by the oddity of the form in which he puts it. Besides this, the work is really sound science and honest teaching, and to all who practice surgery, it tells much which is worth knowing, and tells it in the least possible compass.

Transactions of the Louisiana State Medical Society. Eighth annual meeting. New Orleans, 1886.

This volume of more than 300 pages contains the usual minutes, addresses, and reports, and in addition, a number of original articles of marked merit. Perhaps the most interesting of these are upon the various forms of malarial fever, a topic which occupies several writers. The Society is evidently in a prosperous condition.

"The way to sleep," says a scientist, "is to think of nothing." But Dr. Hammond thinks this a mistake, and adds, "the way to sleep is to think it is time to get up."

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

BIGOTRY IN THE PROFESSION.

In the dark ages, a certain amount of bigotry, of blind, passionate and unreasoning condemnation of that which was distasteful, was naturally to be looked for. The very ignorance of the times bred a narrowness of conception and of judgment, the natural outcome of which would be bigotry. The bigot was abroad in the land; he was found in the halls of worship as well as in the courts of justice, and indeed in every walk of life. But just as bigotry is an accompaniment of ignorance, so, as education and enlightenment began to beam their blessings upon mankind, so by this genial warmth was the man of bigotry thawed out into a reasoning, sensible man; for it will be clearly evident to any one who stops to think about it, that a man *who stops to think* cannot be a bigot; it is the wild, unreasoning, passionate denunciation, or assertion, or condemnation, that is the result or outgrowth of instinct unguided by reason or intelligence, that constitutes bigotry. A man who honestly reflects, and as a result of his calm and honest deliberation reaches a conclusion, cannot possibly be called a bigot. These remarks are called forth by a letter recently received at this office from a physician of good standing, presumably, in this city. He writes concerning the fact that there are two homœopathic physicians on the State Board of Health of Pennsylvania, and after some preliminary remarks, the writer says:

"* * * As you no doubt already infer, I have reference to the homœopathic element both in this Board and in its official organ. We all know that professing to study medicine, or to treat disease by any special system or school, call it homœopathy or by any other name, is simply imposture. The men who are placed in this Board by reason of their proclaiming themselves homœopathists are only the more conspicuously impostors. Special schools in medicine are the device of impostors. *Inexcusable*, therefore, I consider the member of our profession who serves on this Board, or in any other public capacity, with a homœopathic impostor as his colleague. The same objection applies to the publication of the proceedings of the Board. Some of the papers to be published in the "Annals," I perceive, are to come from these very impostors, and I contend that individually and collectively the medical profession is stultified by publishing, or subscribing for the publication, of papers furnished by these whom we know to be frauds. Ignorance in relation to sanitary matters and the doctrines of hygiene is to be deplored, but pray let

our knowledge on the subject be derived from a source not so conspicuously at variance with moral rectitude. Let us not neglect the application of sanitary principles to the moral atmosphere of our would-be teachers."

For a while we were loth to publish this letter, for we were ashamed to let it be seen that such bigotry existed among us. Let it be clearly understood that there is no medical journal in the *world* that more thoroughly condemns the doctrines of Hahnemann than does the MEDICAL AND SURGICAL REPORTER; let us stand fairly and squarely on this question; we do not believe in homœopathy, and we would never consent to submit to its practice upon ourselves, upon those near to us, nor could we conscientiously approve (for reasons given already) of consultations with homœopaths. But, at the same time, we can hardly think that our correspondent will less highly esteem a homœopath than he does a *bigot*. Our complaining friend does not seem to take a broad enough view of affairs to be enabled to recognize the material difference between the science of medicine and the science of hygiene. "Once a Mason always a Mason," is evidently the doctrine of our esteemed friend; "once a homœopath, always and ever and everywhere, on every occasion, and in every relation of life, a homœopath," would be our correspondent's refrain, to which we feel forced to respond, "once a bigot, always, ever, and on all occasions, a bigot."

Now, there are no *schools* in hygiene; when we come to this science, all who pursue it are sanitarians; who ever heard of a *homœopathic sanitarian*, or an *old-school* sanitarian, or an *eclectic* sanitarian? Would our friend sacrifice his religious belief because a homœopath shared in it; would he abandon his usual house of worship (if he has any) lest his spiritual garments be soiled by contact with the hated homœopath who might worship in the same house? Would he refuse to serve, as a charitable and public-spirited citizen, upon a relief committee, because a homœopath has been placed upon the same? If he would, he should be tabooed. We know not our correspondent's religious belief, but, for the sake of argument, let us suppose that he is a Presbyterian: would he consider that he should be ostracized, because he saw fit to serve in an official capacity with an Episcopalian or a Roman Catholic? Yet the complaint that he makes has no more reason in it. This narrow-minded bigotry is totally unworthy of a member of our glorious profession. Let us have done with it. There is an insuperable barrier between the regular practitioner and the disciples of Hahnemann, so far as the practice of medicine is concerned, because they regard disease and treatment from totally different standpoints, and none more thoroughly appreciate and respect this barrier than the editors of this journal. There are also equally insuperable barriers between the Jew, the Mahommedan, the Confucian and the Christian, so far as matters of religious belief are concerned; but when men come together on a common ground, where there is only unanimity of opinion, when they are called upon to unite for philanthropic work, in the nature of which there are no sects, schisms, or isms, then can, and ought, the Gentile and the Jew, the Buddhist and the Confucian, the follower of Zoroaster and Brahma, the homœopath and the regular, meet on common ground and labor for the common good. Such sentiments as our correspondent utters, we are sure, are entertained by but few men to-day, and it is time that these few should realize that such sentiments do not so much express honest convictions as they do unreasoning bigotry. It is this very *blind* persecution that the homœopaths welcome; for the public are not fools, and when any strong party attempts to unreasonably persecute a weaker party, the public are very apt to regard them as martyrs and to champion their cause.

NOTES AND COMMENTS.

Visceral Disorder and Mental Disease.

In the *Brit. Med. Jour.*, Dr. James Adam contributes a case of mental disorder due to the accumulation of fæces in the lower bowel. The patient was a lady, aged 50, who had always enjoyed good health until about three weeks before she came under the author's care. There were great melancholy and mental depression, determined obstinacy, constant restlessness, tossing about and tearing her hair, walking abroad in her night-dress. She was so violent that it was impossible to keep her in any one position for a moment, and she had not slept for several nights. When seen by Dr. Adam she was profoundly taciturn, and refused to take nourishment in any form. There was a history of constipation, and consequently she was given aperient medicines and enemata. She was fed three times a day by means of the stomach-pump. At the end of a week she was no better, and no action of the

bowels had taken place. On examining the rectum, a large hard dense mass of scybala was found; this was broken up, and large enemata were given, so that the lower bowel was thoroughly evacuated. Very soon after free evacuation of the bowels, all the worst symptoms began gradually to disappear, and three weeks later the patient was calm, coherent, and industrious, and quite restored to her natural health.

Hysteria in the Army.

As the result of a series of observations, Dr. Dupouchel has arrived at the conclusion that hysteria is entitled to an important position in the nosology of the army. He considers that many cases of hysteria in the past have been classified either as malingerers or as epileptics. He points out the essential points of difference between epilepsy and hysteria as regards aberrations of the mind as well as of sensation and movement, such, for instance, as the localized anæsthesia or hyperæsthesia, the modifications of the reflexes, and the integrity of muscular irritability as tested by the electric current. The susceptibility of such subjects to hypnotic influences is also alluded to as aiding in the diagnosis. One of the difficulties in the way of a reliable diagnosis is the uncertain advent, and often brief duration, of the "attacks." It is therefore all the more important to arrive at a diagnosis without waiting for a characteristic attack, as the prolonged and often indefinite sojourn in hospitals of doubtful cases is thereby avoided. Catalepsy and somnambulism are now admitted to be presumptive evidence of what might be termed the "hysterical tendency." The complaint, of course, is one of every degree of severity; but it is obviously very difficult to say exactly what degree would incapacitate a soldier for service. One of the most curious facts revealed is the possibility of hysterical paralysis of traumatic origin.

Phimosis in Infancy.

In the *Lancet*, Dr. Hett contributes a few remarks on the subject of phimosis in infants. The author suggests the following rule for those who take charge of midwifery cases: to examine every male child within a few days of birth, and if the prepuce cannot be retracted by the exertion of a moderate amount of force, to perform circumcision on or about the eighth day after birth. Many an unfortunate little boy is credited with bad temper and punished for naughtiness, whose irritability is due to neglected phimosis. There is also much reason for thinking that the old habit of masturbation is frequently led up to by a morbidly excitable condition of the sexual organs, due to phimosis. Circumcision may be performed by seizing the extremity of the prepuce between the finger and the thumb of the left hand, drawing it well forwards, and slicing it off diagonally downwards and forwards, just in front of the glans. The mucous membrane should then be split along the dorsum, quite up to the cervix, turned back, and retained in position by a narrow strip of dry lint wrapped firmly three or four times round the penis. No sutures are necessary. The lint can be removed in a few days, when generally the wound is quite healed.

Standard Pulse-Readings.

In the *Asclepiad*, July 1885, Dr. B. W. Richardson describes his improved sphygmograph, adapted from Dr. Dudgeon's elegant little instrument. The improvements consist in a different method of applying pressure upon the pulse, and a registration of the reading, so that a natural standard may be obtained, and all unnatural conditions may be compared with it. The smooth circular rod of Dudgeon's instrument, which carries the carbonized paper, is replaced by a revolving bar set with a row of sharp edges, which, in revolving on the carbon, cut a series of lines of equal distance from each other along the whole length of the paper. These leave on the paper ten horizontal spaces, each two millimetres apart. At the same time the sharp blades are divided transversely, so as to cut also a series of vertical dotted lines, each two millimetres apart. By this means, the author has found that the standard reading for a healthy pulse has an upright line of precisely the same length as the horizontal distance between each beat of the pulse, and that from the first point of impulse to the last point of movement is a square of four and a half spaces, or nine millimetres.

Neuralgia of the Pudendal Nerve.

Professor Adamkiewicz, of Cracow, reports (*Medycyna*, April 26, 1886; and the *Vratch*, No. 26, 1886,) an extremely rare case of neuralgia affecting the pudendal nerve alone. A previously healthy woman, about three years before coming under the author's observation, and about two months after her second labor, began to suffer from an intense "tying together" pain in her

urethra during micturition. Subsequently, the pain spread over the bladder and became almost incessant; it grew worse from every movement and emotion, and was now associated with calls to pass urine. There were present two painful and tender points; one was situated at the apex of the angle formed by the sciatic tuberosity and an edge of the great gluteus muscle; another was found at a spot on the inner surface of the ascending ramus of the sciatic bone. The treatment adopted by Professor Adamkiewicz consisted in galvanization (daily sittings of several minutes' duration), the anode being applied between the tuberosity and spine of the sciatic bone, and the cathode to the sacrum or to the pubic symphysis. A complete cure followed after three months' treatment.

Sterility from Obesity.

The patient, a Jewess, aged 28, married eight years previously, consulted Dr. Brondel on account of her inability to become pregnant. She was extremely fat, her abdomen being very pendulous; and an enormous aggregation of adipose tissue completely hid the external genitals. On examination, the uterus and its appendages were found to be healthy. The patient was put on a rigid dietary for a period of eighteen months, in which time she lost 20 kilogrammes (44 lbs.) of weight. At the same time the menses, which before had been scanty and far between, became more frequent and abundant. Soon afterwards, she became pregnant. Sickness was troublesome for some time, but yielded to a few doses of cocaine ($\frac{1}{12}$ grain). Labor came on in due course, but the first stage very tedious, and eventually, as the second stage was the signal for total arrest of uterine contraction, the forceps had to be applied. With a great deal of difficulty a female child was extracted, but it had two club-feet and deformed hands, together with an enormous spina bifida. The heart was still beating, though asphyxia was imminent; but, on account of the deformities, Dr. Brondel did not think it desirable to make any effort with a view to restoring animation. The difficulty in effecting delivery was due to the doubling back of the right arm behind the neck, a fact which was only diagnosed when it was seen.

Case of Labor Obstructed by Cyst of the Ovary.

Marie L., aged 27, a dressmaker, was unable to assign the date of her pregnancy, as menstruation had never ceased. She had already given birth to one child at five and one-half months. On admission, January 7, 8 a. m., a breech presentation was diagnosed by abdominal palpation. The cervix was displaced forwards against the symphysis. Behind it was found a tumor, in the posterior *cul-de-sac*, situated in the median line, but more marked on the right side. It evidently contained liquid, but its size could not be exactly ascertained. Labor did not advance, and a discharge of meconium occurred several times. At mid-day, M. Porak punctured the tumor from the vagina with a trocar two mm. thick. About four hundred grammes of a viscid ropy fluid came away, and the tumor could no longer be perceived. Labor then went on satisfactorily, and at half-past one delivery of a dead child took place. Convalescence took place without any unfavorable symptoms. The liquid drawn off, when analyzed, proved to contain the principal elements of the bile, but no cholesterin.

Ataxic Paraplegia.

In a recent number of the *Archives de Neurologie*, M. Grasset of Montpellier concludes a paper on the subject of combined posterior and lateral sclerosis of the cord. The contribution is mainly one of a clinical character, and aims at throwing light on the symptoms of mixed varieties of myelitis. The author is of the same opinion as Dr. Gowers, that on clinical and pathological grounds the creation of a new name and separate consideration of the disease are desirable. M. Grassett proposes the term "combined tabes"—a name which is far less appropriate than that of ataxic paraplegia. But there seems to be some difference of opinion as to the range of symptoms. The English observer asserts that the lightning pains of true tabes are of rare occurrence in the combined sclerosis, whereas the French author states that, symptomatically, "combined tabes" is characterized by the association of symptoms of ataxic tabes (lightning pains, anæsthesia, motor incoördination) with symptoms of spasmodic tabes, etc.

Rupture of the Bladder.

The result of suturing the rent in cases of ruptured bladder has not hitherto been successful, but the opinion held by surgeons, that it is the right treatment to pursue in such cases, receives strong confirmation from a case now under the care of Sir William MacCormac in St. Thomas's Hospital. The patient, a strong, florid, healthy man, aged

thirty-three, injured his abdomen by running up against a post, about fifteen hours before he applied for admission. Interrupted silk sutures were used for the bladder, the rent in which was about three inches long, a catheter was tied in, and the abdomen drained by a glass tube. There was a large amount of urine in the peritoneal cavity, which was washed out with a solution of boracic acid. The operation was performed on the 22d ult. The patient passed urine the following day, when the catheter was removed. The drainage-tube was taken out on the 24th, and there has been no fever or other symptom since the operation.

Double Fracture of the Upper Limb by Indirect Violence.

The following is noteworthy as a somewhat curious result of indirect violence applied to the upper extremity:

A child, aged nineteen months, was being led along the street by his mother, who was holding his right hand. The child stumbled, fell with a jerk, and was dragged up again —roughly, probably—by his mother, who, however, never let go of his hand. She then noticed that the boy's arm was quite powerless, and hung loosely by his side. Shortly afterwards the child was brought to the infirmary, where Dr. Alex. Foulerton (*Lancet*), found that two fractures had occurred, one through the upper epiphyseal line of the right radius, the other at the junction of the middle with the acromial third of the right clavicle. One would certainly have expected dislocation rather than fracture as the result of such an accident occurring in so young a child, and he is unable to offer any exact explanation as to the mechanics of the lesion.

Rectal Injections of Medicated Gases.

Rectal injections of medicated gases as a method of treatment is based on a physiological principle established by Claude Bernard, that the introduction of toxic substances into the rectum is not dangerous so long as pulmonary elimination is perfectly normal. Dr. Bergeron has adopted this method of treatment in several affections, and publishes the results obtained in pulmonary phthisis. A current of from four to five litres of carbonic acid gas is passed through 250 to 500 grammes of mineral water, containing sulphur (Eaux Bonnes, Allevard, Saint Honoré, Callas), and then introduced into the rectum: in the course of 24 hours two injections are made. After two days had elapsed this treatment had cured the cough which troubled the patients; expectoration was also modified in quantity and character. The profuse perspiring of phthisical patients was removed, and their general condition improved, even in the confirmed stage.

Velamentous Insertion of the Umbilical Cord.

The placenta in question followed a perfectly normal labor at the *Maternité*, and presents the peculiarity that the umbilical cord, instead of being inserted on to the placenta, abuts on the membranes eight centimetres from its edge. It at once divides into two branches, each composed of a vein and two arteries; these vessels subdivide dichotomously, and after a winding passage of about 20 centimetres reach the placental edge over about three-quarters of its circumference. The occurrence is very rare, and has given rise to a good deal of discussion as to its cause. It is sometimes possible to diagnose it during labor by feeling the abnormal pulsation of the umbilical vessels. The risks this arrangement entails are obvious; the vessels may be compressed and so cause the death of the child, or they may be lacerated and cause severe fœtal hemorrhage; the remedy for either condition being expedition in effecting delivery.

Membranous Compound Diphtheria.

In the *Brit. Med. Jour.*, June, 1886, Dr. W. J. Mackie relates a case of a membrane appearing on the glans penis, which he compares with a similar case related by Dr. Leslie Phillips in the *Journal* of June 5. Dr. Mackie circumcised a child, and next day found a membrane having the appearance of a thick yellowish-white paper extending over the mucous membrane in the region of the frænum. This exudation seemed identical with that of croup, in being easily detached, and involving only the epithelium, and not the subepithelial tissue, as in diphtheria. Dr. Phillips has reported a similar case which he considered diphtheritic, as he had performed tracheotomy with the instruments used in the circumcision. Dr. Mackie, however, draws attention to the marked asthenic symptoms of diphtheria and the sthenic reaction of membranous croup.

Antifebrin.

Antifebrin, as the *Pharmaceutical Journal* points out, is a new antipyretic, that belongs to a very different group of chemical substances than those from which antipyretics

have hitherto been drawn. The class of phenols has supplied us with carbolic acid, resorcin, hydroquinone, salicylic acid, and besides these are the bases like kairin, antipyrin, thallin, and quinine. Antifebrin is a neutral body, and identical with phenylacetamide or acetanilide, almost insoluble in cold water, but freely soluble in wine and alcoholic liquors. On dogs and guinea-pigs large doses seem to have no deleterious action. The substance has been administered to twenty-four fever patients (the kind of fever is not mentioned) in doses of not more than two grammes in the twenty-four hours, and with such satisfactory results that a quarter of a gramme is said to be as effective in reducing the abnormal temperature as a whole gramme of antipyrin.

A Successful Case of Nerve-stretching for Facial Spasm.

In the *Lancet*, Mr. Southam writes to say that a patient whose facial nerve he stretched in 1881 has remained well ever since. The operation was followed by complete paralysis of all the muscles supplied by the nerve. About five weeks afterwards, the affected muscles gradually began to regain their power, and at the end of five months the paralysis had entirely disappeared. In a recent article by Professor Zesas, particulars are given of nineteen cases of this operation. In only two instances did the operation succeed. In four cases there was considerable improvement, in ten only temporary relief was obtained; the remainder were lost sight of. Zesas is of opinion that the operation should be performed whenever the spasm is not due to intracranial lesions.

Exploration of the Bladder by Section through the Perineum.

In the *Lancet*, August, 1886, Professor Henry Smith draws attention to what is known as the operation of cystotomy. The author, however, objects to this term, as in the operation so named the bladder is not cut into; an incision is made through the perineum into the membranous portion of the urethra, through which the bladder is examined, and any foreign body removed; the bladder can then be drained by means of a tube fixed in the opening, thus giving the bladder complete rest. In cases of long-standing cystitis, or where there is some growth causing irritation of the bladder, this operation is one of the most valuable aids to surgery. In cases of malignant disease of the bladder much relief can be given to the patient by thus keeping the bladder free from urine.

Grafts of Frogs' Skin.

In spite of an unfavorable experience of skin-grafting in burns, etc., Professor Morales Perez tried in a case of burn of the hand the lately recommended plan of engrafting frogs' skin. Three quadrangular grafts, two centimetres wide by three long, were first applied, medicated wool and iodoform ointment being the dressing used. After five days these grafts were found to have adhered, with the exception of two small bits. Two fresh grafts were applied in other points, and these adhered well. After some days the epidermis and the blackest green pigment of the graft dried up and was detected in fine scales, leaving a thin white cicatrix. Finally a very satisfactory elastic cicatrix was obtained, the line of the grafts being visible.

Case of Dangerous Hemorrhage from the Hymen after the First Coitus.

In the *Meditz. Obozr.*, No. 10, 1886, Dr. P. G. Rozanoff, of Zvenigorod, reports the case of a newly-married peasant woman, aged 18, who was brought to the local lying-in hospital in the state of extreme acute anæmia, on the third day of incessant hemorrhage from the hymen, which had been ruptured during the first coitus. The hymen, of a semilunar variety, presented a single but complete laceration on the left side. The bleeding, which was moderate and of a parenchymatous nature, was easily arrested by pressure with a cotton-wool plug, the patient leaving the hospital in a satisfactory state, after a three days' stay.

Hysterical Hemiplegia in a Child of Four Years.

At a recent meeting of the Paris Biological Society, M. Gayot read the following note: A child, aged 4, perfectly free from any nervous symptoms, was, after undergoing violent agitation, seized with hemiplegia of the right side and aphasia; the motor and sensory faculties were impaired. A few days later on, the hemiplegia disappeared, but reappeared the next morning; the following night, the sensory and motor faculties regained their normal activity; the child's health has since remained excellent. Her mother has an excessively nervous temperament, and she is the daughter of gouty parents; the father is also highly nervous in temperament. Each return of hemiplegia in the child was accompanied by aphasia.

The Use of Antipyrine during Pregnancy.

Professor Chiara (*Ann. di Ostet.; Réport Univers. d. Obstét. et Gynéc.*) draws the following conclusions from the use of antipyrine in the cases of twelve pregnant women, five of whom had gone to full term :

1. In therapeutic doses it has no particular oxytocic action.

2. Pregnancy, whether normal or pathological, does not modify its action.

3. It may be used with perfect safety as an antipyretic during pregnancy.

4. Like other antipyretics, it may tend to prevent abortion, an excessively high temperature being a frequent cause of that accident.

Prevention of Drowning.

Referring to the bathing season, Dr. Ziegler, of Switzerland, urges medical men to give as much publicity as possible to the "warning symptom," consisting in the appearance of a deep-red coloration of the skin in the bather. The symptom being a sure foreteller of coming syncope, the bather attacked with it must be at once compelled to get out of the water, even if he or she feel well at the moment. Many a life may be saved by paying a due attention to that sign, which was first pointed out by French military surgeons.

Remedies for Coryza.

Roben (*Gaz. Med. de Bordeaux*) recommends the following powder for insufflation :

℞.	Powdered menthol,	gr. iij.
	Roasted coffee,	ʒj., gr. xv.
	White sugar,	ʒj., gr. xv.
M.	Sig.—Snuff.	

The above mixture has the appearance of snuff, and is easily employed. The following is also recommended :

℞.	Hydrochlorate of cocaine,	gr. iss.
	Browned coffee,	
	White sugar, āā	ʒiss..
M.	Sig.—Snuff.	

Nervous Cough.

This mixture is highly recommended for nervous cough :

℞.	Cocain. hydrochlorat.,	gr. j.
	Potassii chlorat.,	gr. x.
	Aquæ amygdal. amar.,	♏x.
	Aquæ destillat.,	fʒiss.
M.	Sig.—To be used as a spray.	

Lotion for Rhus Poisoning.

Dr. E. Mommsen, of Bloomington, Ill., writes to the *Medical Record* that immediate relief to the patient poisoned by *rhus venenata* followed the local use of

℞.	Carbolic acid,	gr. x.
	Boric acid (powdered),	ʒij.
	Vaseline,	ʒj.
M.	Apply two or three times daily.	

Mammary Neuralgia.

At a recent meeting of the Paris Surgical Society, M. Routier read notes on a case of intense mammary neuralgia; the patient was 22 years of age. A small tumor of the size of a nut was removed, and the pains completely disappeared. On microscopic examination, the tumor presented the characteristics of polyadenoma.

Correspondence.

The Physiological Action of Opium upon the Intestinal Tract.

Eds. Med. and Surg. Reporter:

In Ziemssen's work, vol. viii., page 280, the writer, Bauer, puts forth the teaching that opiates, instead of *arresting* peristaltic action *increase* that movement. I would like to hear through the medium of the Reporter, what the scientific teaching at present is upon the physiological action of opium upon the intestinal tract. If Bauer is right, then all previous teachings concerning that particular property of opium have been wrong. I would also like to know what construction the author would want to have put upon the sentence "If opium did arrest peristaltic action, the practical results which, as a matter of fact, follow its administration in the treatment of peritonitis would not be attributable to it." Strike out that portion of the sentence from "results" to "would," and any arrest of peristaltic action is denied opium, *while in the expunged portion it is admitted.* The sentence is surely a contradictory one. J. K. Ewing, M. D.

Delmont, Westmoreland county, Pa., October 6, 1886.

"Induction of Premature Labor."

Eds. Med. and Surg. Reporter:

With reference to the above subject in your issue of this week, I would say that the method by which Dr. T. Gaillard Thomas induces premature labor is old, and as he says, "a perfectly efficient one." Twenty years ago I first performed this little operation, with the injection of water and

a gum catheter; with this addition—I gave after the operation a fresh infusion of ergot of rye with borax.

H. Isaac Jones, M. D., L. R. C. P. E., etc.
Scranton, Pa., October 12, 1886.

Admitted to the Sight, Why Wouldn't You Smile?

Eds. Med. and Surg. Reporter:

The following is a list of the remedies employed by an Æsculapian aspirant to fortune and fame, in combating what he called "slow fever," which was preying upon the vitals of a six-months-old infant, and the only thing that marred the M. D.'s diagnostic skill was the premature death of the little innocent: Calomel, quinine, bismuth, brom. pot., ammonia, fl. ext. nux vomica (3 drops in 12 hours), fl. ext. digitalis, chloroform, spts. turpentine, nitre, squills, carbolic acid (4 drops in 24 hours), assafœtida, alcohol, mustard, enema, medicated bath—and the Lord only knows what else.

Young M. D.

Wallaceburg, Ark.

News and Miscellany.

A Prescription Book of the Eleventh Century.

Medicine has her archæology like every other learned vocation, and hardly a year passes without adding to her treasure-trove. In one of the precious MSS. contained in the Capitular archives of Ivrea, in Piedmont, Prof. Piero Giacosa has found a book of receipts which remounts to the eleventh century. The professor discourses learnedly on this book, pointing out, amid the scarcity of medical writings at that remote date, the importance of a document which adds to the proofs—authentic, if rare—that the ancient Græco-Latin tradition of medicine was still preserved, and that it may have given origin, without the intervention of Arabian medicine, to the famous school of Salerno. The MS. in which the book is inserted belonged to Warmund, Bishop of Ivrea, famous even in the first years of the stormy eleventh century for his love of science and literature. Before the prescriptions comes a group of receipts for writing with gold, for making gold ink, and for illuminating parchment. Then follows a catalogue of maladies, thirty-two in number, more than half of them relating to the eyes, while the remainder have reference to the head, the ears, the throat, the kidneys, and so forth. Each malady has its remedy—one or more—the majority belong to the vegetable kingdom, though the the animal world supplies not a few. Among the latter we have fat of eels, raw flesh, the gall of a great variety of animals, such as the eagle, the cock, the hyæna, the hare; then goat's dung, hartshorn, serpents' skins, worms, etc. The vegetable remedies include aloes, camphor, cassia, lettuce, honey, opium, sundry aromatic herbs, rue, linseed, mustard, and so on. Finally come a few chemical and inorganic remedies: orpiment, lime, nitre, sulphur, French soap, etc. According to Prof. Giacosa the medicines are mostly derived from Dioscorides and Pliny. He also finds a correspondence, in the matter of arrangement, between the prescription book of Ivrea and the work of Lucius Apuleius Platonicus on the virtues of herbs—a work of which the compiler of the prescription book availed himself as a guide, and of which the Chapter of Ivrea doubtless possessed a copy now lost. The original part of the prescription book betrays a scientific turn of mind in advance of the age as to the conception of disease and the *modus operandi* of remedies. The author signs himself "Petrus Magrus"—probably a fictitious name, it having been the frequent habit of early mediæval writers on medicine to assume the surname "magrus" (lean), an epithet, according to Prof. Giacosa, which implies a not very lucrative practice. The importance of the professor's discovery, as we have said, lies in its demonstration that in Italy the Græco-Latin tradition in medicine was never lost. In fact, in the Ivrea MS. there is mention of but one remedy due to the Arabs—to wit, camphor. This drug, isolated among the others, proves that while in the eleventh century the Arabian pharmacopœia was not unknown, it had not yet, as a whole, taken root in Italy.

Fees of Noted English Physicians.

The *Boston Traveler* thus notes from a London letter:

"'Do London doctors earn more than than queen's counsel?' As a rule they do not, but the incomes of the three leading physicians and those of the three leading lawyers are about equal—that is to say, at the rate of $60,000 a year each. The largest sum ever earned in one year by a doctor was $100,000, made by Sir Astley Cooper. The three men at the head of the medical profession in England at the present day are Sir William Jenner, the court physician, Sir William Gull, and Sir Andrew

Clark. Just lately the last named has obtained considerable notoriety. He was induced to visit a very wealthy lady at Nice, and he received the unprecedented fee of $25,000. One-fifth of this amount he retained as a remuneration for his services, and the remainder he divided between two charitable institutions connected with his profession.

"Speaking of fees, there is a tale told of a rich colonial gentleman living in Kent, who had the misfortunne to take a slight cold. Not satisfied with his local medical attendant, he desired to have Gull down from London in consultation. Gull happened to be away, and Sir William Jenner came instead. He was duly paid his fee of $375 for the visit. The patient, feeling no better, then sent to Edinburgh to a leading doctor of that city, who traveled the 400 miles in order to see him, and in ordinary course received a guinea for every mile—that was 400 guineas, or $2,100. Again the patient felt no better, and this time Gull was summoned and attended.

"'I suppose,' suggested the local practitioner, 'you will pay Gull what you paid Jenner—$375?'

"'Nonsense,' indignantly retorted the sick gentleman; 'I am not going to pay Gull less than I gave the Scotchman,' and he drew a check for $2,100. Before he got rid of his cold he had paid $7,000 in fees."

"The Protean Man."

Some wonder is being excited in the provinces of France by the exhibition of an individual who dubs himself "L'Homme-Protée." The number of shapes and attitudes that the man is able to assume is said to be so great to be so great that the title of "Protean" may well be allowed if the individual manifests only half the powers attributed to him. Now, whatever he can do, it is obvious that his faculties are the same in kind as those possessed by the rest of mankind, though the degree in which the faculties are developed may vary vastly; so that we can not agree with the writer who asserts that the contortionist transforms himself, thanks to his *peculiar* system of muscles. Doubtless his frame is wonderfully mobile, and every part of his nerve and muscle apparatus has been trained to the utmost. It is possible, also, that M. Aiguier is gifted with the power of influencing the action of muscles over which man usually exercises no voluntary control, though with practice many may acquire the capacity if they set themselves about the task in the proper fashion. The Protean man, it is said, can assume the rigidity of a statue, so that, the body sharply struck, the blows fall as on a block of stone. This probably means that the man has the capacity to develop at will the cataleptic condition. By varying the activity of different muscles of the abdomen he is alleged to be able to give his trunk a great variety of shapes and sizes, from that of the proverbial alderman to that of the lean and haggard student. He is even accredited with the possession of the power to appear as lean as a skeleton; but this must surely require an effort of the imagination, as well as a still greater effort on the part of the muscular and vascular apparatus of the contortionist. What most astonished M. de Quatrefages, who examined him, was the ability to stop the flow of blood, now on the right side of the body; this was ascribed to the influence of unilateral muscular contraction.

A Memoir of Austin Flint, M. D., LL. D.

A memoir was read by Dr. W. M. Carpenter before a recent meeting of the Medical Society of the County of New York. The following quotations from the memoir (*N. Y. Med. Jour.*) refer to Dr. Flint's private character: "On one occasion he said to the author, 'It is a positive enjoyment for me to write, and when the work of the day is done I sit in my office and frequently write until 11, 12, 1, and perhaps 2 o'clock, before I feel tired enough to go to bed.' The result of this labor, yet his pleasure, was the numerous articles for medical journals, papers to be read before medical societies, addresses before learned and scientific bodies, and several volumes on subjects belonging directly to our science and art, all of which reflected credit upon their author. He wrote with facility, his style was finished, and his diction was classical. * * He won the respect, the confidence, and the admiration of his pupils. His lectures were characterized by graceful delivery, simple but expressive language, and systematic presentation of his subject. * * He rarely lectured or spoke on medical subjects without preparation. * * Gentlemanly deportment was his constant attendant. Dr. Flint was a man of simple habits, polished manners, independent opinions, and freedom from fear in their advocacy, and indefatigable industry, of whom it can be said truthfully that 'he possessed a capacity equal to any occasion which might arise.' * * He was affable and indulgent, and was always ready to throw around the beginning practitioner

the strong arm of his protective power and sympathy."

Newspaper Therapeutics.

The custom of giving medical advice in the newspapers has of late years become a somewhat common one. Whatever motive of expediency may be urged in its favor by those whose practice it is, more than enough for its condemnation may, we are sure, be said on the other side. There are many points in diagnosis which can only be made out by personal examination; nay, statements in this connection are commonly of little value. Even facts of life history cannot always be correctly learned from a written description. There is, therefore, inseparably connected with this singular mode of practice the danger of misinterpretation, the unfortunate results of which may at any time react upon the patient. We may be told that if care be taken to select simple cases, no serious evil can arise. The argument even so put, however, is a weak one. It amounts to this, that where the ailment is slight, it does not matter much if a little mischief is done. By it a wrong principle is not excused by the impotence of its practice. The trifling ailment, moreover, may be aggravated by delay or mismanagement, while even a cautious beginning in such haphazard treatment will often become the cue for heedless enterprises of a like kind. It will also be seen that while the tendency of such procedure is to debase the quality of medical advice, its effect must be to augment the already inordinate value which is assigned by many to drugs and other means of cure in themselves.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR TWO WEEKS ENDED OCTOBER 9, 1886.

Peckham, C. T., passed assistant surgeon. Granted leave of absence for thirty days, to take effect when relieved, October 5, 1886.

Kalloch, P. C., passed assistant surgeon. Granted leave of absence for twenty-one days, to take effect when relieved, October 5, 1886.

Pettus, W. J., assistant surgeon. To proceed to Evansville, Indiana, for temporary duty, October 8, 1886.

Kinyoun, J. J., assistant surgeon. Appointed an assistant surgeon, October 4, 1886. Assigned to temporary duty at New York, N. Y, October 5, 1886.

Urquhart, F. M., passed assistant surgeon. Relieved from duty at Cape Charles Quarantine, to proceed to Washington, D. C., with steamer "Woodworth," October 20, 1886.

Wasdin, Eugene, passed assistant surgeon. Promoted and appointed passed assistant surgeon, from October 1, 1886, October 20, 1886.

Williams, L. L., assistant surgeon. Granted leave of absence for three days, October 16, 1886.

The Progress of Homœopathy.

The *Med. Record* says that the homœopaths have heen holding an International Congress at Basle, Switzerland. It was the Third Quinquennial Congress, and was attended by only forty delegates, of whom seven were from America. The sessions seem to have been largely occupied with persuading the members that homœopathy is growing. It would take a brave heart, however, to find encouragement in the various reports presented. Thus, by their own figures, we learn that in France there are but 200 homœopaths, in Belgium about 60, in Switzerland 23, in Spain 137, while in Germany and England the reporters do not venture to estimate the number. Judging from the statistics given, it would be a large estimate to suppose that in all Europe there were 1,000 homœopaths.

The real hope of homœopathy appears, therefore, to be in this country. Here, it is stated, there are over ten thousand homœopathic practitioners, with fourteen medical colleges, fifty-one hospitals, forty-eight dispensaries, one hundred and forty-three societies, twenty-two journals, and thirty-three pharmacies. There is no doubt that the United States is infested, beyond any other country, with the silliness of attenuations and potentializations. It appears to be one of the social disorders to which new countries are subjected, but it is one which, dispite the apparent showing of statistics, the United States is surely outgrowing.

A Doctor's Tale of the American Civil War.

Dr. Robert St. George Dryanforth, of Washington, relates a curious experience of his own during the war of the rebellion, and later, while acting as a correspondent in the Franco-German war. While serving in the first great struggle, the doctor was shot through the lungs and was invalided. He subsequently went to Europe for his health, and remained there for some years. When the German war broke out he became cor-

respondent for the *New York Tribune*, and in one of the battles he was shot through the base of the skull. He caught a heavy cold while lying wounded on the battle-field, and his wound in the lungs troubled him so much that his life was despaired of, and he was a victim of rapid consumption. One day during a violent fit of coughing the doctor brought up a piece of his overcoat, which had been shot into his lungs ten years before. The ejection of this cause of irritation so relieved him that he at once became better, and finally completely recovered. He returned to Washington, and has since held the office of Judge of the Court of Appeals. He was also a member of the Board of Examiners, and Assistant Commissioner of Patents.

Doctoring an African King.

The following extract is from the correspondence of the *Scottish Geographical Magazine:*

"It is no joke to be doctor to the King of Uganda, for whenever I took him a new supply of medicine I had always to take a dose myself, and to administer one to seven of the persons who might happen to be present. Should one of the seven unfortunates die within a week, it would be considered that I had attempt to poison the king. If the king had to take a pill, I had always to hold two in my hand; he chose one, and I had to swallow the other, unless I had a friend with me who kindly undertook the office. I soon noticed, however, that Mtesa also chose the smaller, so I arranged accordingly. One day Mtesa played me a nice trick. I had been to the palace to take him a lotion, and had warned him particularly not to drink it. After I had left he sent a page after me with a gourd of mwengi, asking me to taste it, and say if he might have some. I did so, and said, 'Yes.' It being a very hot afternoon, my friend drank the remainder; but it soon became evident that the king had doctored the wine, for my friend became violently sick. It turned out afterward that Mtesa wished to see what effect the lotion would have upon me."

Discovery of Primitive Skulls.

It is announced that MM. Marcel de Puydt and Maximilian Lohest, of Liege, have found in the sandstone in a cave at Spy, a few miles from Namur, known as the Biche aux Roches, two human skulls of extraordinary thickness, resembling the celebrated skull found in the Neanderthal, near Elberfeld. They suggest that these are types of the skulls of the primitive race who dwelt on the Sambre. Other things were discovered in the cave, among them some thousands of flints very carefully dressed on one side; also some specimens of jasper and agate, minerals not found anywhere in the neighborhood, ivory breast-pins, several red ear-pendents, and some necklets of pearls of curious designs. All were found in the sandstone, three layers of which were plainly discernible. The remains of flints, etc., deposited in each layer, indicated different stages of skill in workmanship. The lowest stratum was by far the poorest in the number of the objects found and in the quality of their workmanship. But it was here that the skulls were found.

Antiseptic Treatment in the Bulgarian War.

M. Maydl states that of 3,000 men wounded in this war, who were brought to Belgrade, only 51 died; of these, 22 deaths were the result of tetanus; the surgical mortality was only 0.9 per cent., thanks to the use of antiseptic dressings. This result is the more remarkable as the sanitary condition of the soldiers was very defective. Cases of erysipelas were also very rare, and in spite of the want of care on the field, M. Blum reports that of 136 cases, of which 116 were lance or sword wounds, 12 complicated fractures, and 10 articular wounds, all treated antiseptically, there were no deaths or purulent diseases. The dressings were done with carbolic gauze, at .5 per cent., and the instruments washed with disinfectant fluid at 25 per 1,000. After the first day the wounds were aseptic. This war has, therefore, done much to let us know the value of antiseptic treatment in military surgery.

A Novel Obstetrical Expedient.

Dr. Shustoff writes in *Russkaya Meditsina* of April, 1886, that he was called to see a woman who had been in labor five days. The pains had begun well, but had since ceased. Upon examination he saw something black protruding from the anus, and a little pulling brought to light a sausage over seventeen inches long and fourteen inches in circumference. The pains now began again, and the woman was soon delivered of a dead child. Dr. Shustoff found on inquiry that the sausage had been introduced on the recommendation of an old woman of the

neighborhood, in order to insure the birth of the child by the normal passage. This was probably the old wife's best attempt at supporting the perineum.

He Snatched Her from the Grave.

An old member of the medical profession in Chicago tells the *News* of that city a story, which, he says, Dr. J. Adams Allen told him many years ago. Dr. Allen, as the story goes, was just beginning his practice, when, one winter day, seated in a car, muffled to the ears, he heard the following conversation between two passengers who were sitting where they could not see his face: "Say, George," said one, "what kind of a doctor is this young Allen?" "All I know about him is that he snatched my aunt from the grave last summer; that is, I shall always think he did." "Did he, indeed," said the other, "well, he must be a pretty good doctor, then. What was the matter with your aunt?" "Oh, she was dead and buried, you know."

The Traffic in Rags in Holland and Switzerland.

The Netherlands Government have issued a ministerial notification prohibiting, from August 27, 1886, the importation and the transit of rags, worn clothing, and unwashed underclothing and bedding, coming from Italy and Austria-Hungary. Worn clothing brought by travellers as part of their baggage does not come within the prohibition. The Swiss Federal Council have also prohibited, by an order of August 20, and until the issue of a further order, the importation and transit of rags, old clothes, unwashed linen, etc., coming from Italy, except such as may be included in travellers' baggage.

In the Pharmacy.

Mr. Oppenheimer.—"Rachel, haf ve got mooch of dot gholera migscher auf der sheluf?"

Mrs. O.—"Yaw, Isaac, dere is two grosses of bottles of der migscher."

Mr. O.—"Vell, send Schakey out for a parrel of green apples, und ve vill gif dem avay to der small boys der neighporhoot in. Hast du gesehen? Ve must dot peeziness poom alretty."

Personal.

—Dr. D. Hayes Agnew has purchased the residence of Dr. R. J. Levis, on the northwest corner of Sixteenth and Walnut streets, Philadelphia, and has removed his office to this place. Dr. Levis has gone to Europe for a prolonged stay.

Items.

—A scientific society at Haarlem (Holland) offers a gold medal and 400 florins (about $165) for the best treatise, which may be written in English, on the researches of M. Pasteur, to be sent in before April, 1887.

—Miss Hastings, of England, aged one hundred and five, is the banner girl for recuperative power. At the age of 104 she had a double pneumonia, from which she made a good recovery, according to Professor Humphrey, of Cambridge.

—A successful experiment in distilling ottar of roses grown in Germany is reported. A firm at Steinfurth obtained from 25 kilos of the petals of *Rosa centifolia* 16 grams of ottar. Similar quantities of petals from other roses yielded only 6 grams. The ottar is said to have been superior to the Turkish in aroma.

—To prevent the surreptitious opening of of letters or papers, it is recommeded in the *Bulletin Commercial* to stick together the glued parts with ammoniacal oxide of copper, which reagent superficially dissolves the cellulose. In another way, the same result may be obtained by using silicate of potassium, which, once dried, cannot again be dissolved in water.

—On the 7th of November Harvard University will have completed its 250th year. It is proposed to celebrate the event in a suitable manner from the 6th to the 8th of that month. Harvard University was established by an act of the Colonial Legislature, and was named in honor of John Harvard, who liberally endowed it. With one exception, Harvard is the oldest university in the New World. Nearly one hundred years before, in 1551, the Emperor Charles V. established the University of St. Mark's, at Lima.

QUERIES AND REPLIES.

Wickersheimer's Fluid.

Eds. Med. and Surg. Reporter—

In glancing over an old file of Reporters, I notice in Vol. xliv., January 8, 1881, a formula for Wickersheimer's Fluid. I would like to ask if this is a formula for embalming dead bodies, how originated, and if superior to other embalming fluids. Please answer through columns of Reporter, and oblige W. N. Sherman, M. D.

Winslow, Arizona.

Reply.—We have no further information than that contained in the article referred to. We would be pleased if any of our readers can enlighten our correspondent.

Eds. Med. and Surg. Reporter.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

DR BUCKLAND'S SCOTCH OATS ESSENCE

NATURE'S NERVE TONIC AND BRAIN FOOD.

Yielding the most remarkable results in both Functional and Organic Diseases of the Brain and Nerves, especially

NEURALGIA,	OPIUM and MORPHINE HABITS,	SPERMATORRHŒA,
INSOMNIA,	INFANTILE PARALYSIS,	TIC DOLOUREUX,
SCIATICA,	NERVOUS DYSPEPSIA,	MELANCHOLIA,
MANIA,	NEURASTHENIA,	IMPOTENCY.

FORMULA.—Avena or Avenesca, the active principle of the Oat (Avena Sativa) obtained by crushing the grain (dried in vacuo) with pure alcohol, skimming off the fatty scum obtained by ether washing, evaporating to dryness, and then dissolving the amorphous powder (Avena) with boiling alcohol and flavoring. The dried grain is then treated by maceration and percolation from 96 to 144 hours. The final solution is of a 3⅛ per cent. strength.

☞Most remarkable cures of the OPIUM HABIT.

☞The most active tonic to both male and female SEXUAL ORGANS known.

☞Almost Specific in IMPOTENCY and SPERMATORRHŒA.

☞As a Brain and Nerve Tonic and Restorer of Wasted Energy it is unparalleled.

Put up in 6 oz. bottles. Price, $1.00. For sale in all drug stores.

SCOTCH OATS ESSENCE COMPANY, 174 Fulton Street, New York.

FURUNCULOSIS.

BY JNO. A. STAMPS, M. D.,

Of Wallaceburg, Ark.

In a seeming obedience to the old saying, "It never rains but it pours," we are frequently visited by diseases in an epidemic form, some of which are enveloped in obscurity when we come to look up their mode of origin and propagation. The latest and seemingly most troublesome epidemic which has made its appearance in our vicinity is that of furunculosis. Quite a number of our inhabitants have for the past few months been the subjects of this, I may say, rather loathsome disease, and when occurring in an individual it has most generally kept him nursing one of its "pets" for from a few weeks to a month or more by successive crops.

It may be defined as an inflammation occupying the entire thickness of the skin and subcutaneous connective tissue, and attended almost always with circumscribed suppuration and the formation of a slough. Boils and carbuncles are considered by some to be a local affection produced by local causes, and like acne mainly an affection of the sebaceous glands; but from the fact that when a person becomes the object of their prey they continue having them for some time, and as they occur in situations that are comparatively free from sebaceous glands, as the palms of the hands; and again, as they do not show any special preference for attacking the scalp and face, where these glands are most numerous, I am inclined to think that this theory is incorrect, and am further of the opinion that it is a constitutional disorder with local manifestations, and while they are common in persons of a broken down constitution, they nevertheless affect those who are of an undoubtedly healthy constitution, and in a manner free from the more prevalent maladies.

The morbid process in some instances begins with the formation of a small vesicle developing into a pustule which contains a drop of thick pus, and others begin without the formation of the vesicle, but present a somewhat nodular appearance. In both varieties there is an infiltration and induration of the deeper structures of the skin, attended with swelling and redness of the surface. This swelling increases more or less rapidly in area till at the end of from a few days to a week or more it has attained its full degree of development, at which time it presents a more or less circular base and a rounded or pointed apex, and varies in size from a filbert to an egg. It is intensely congested, and surrounded with an areola the hue of which varies with the intensity of the inflammation, the amount of tissue involved, and the stage at which it is seen.

If allowed to go on to suppuration, which is the inevitable tendency, it will be discovered upon opening one that a slough has been gradually forming during its progress which has involved the deeper structures of the skin and connective tissue. The slough presents a yellowish or grayish color bearing a faint resemblance to wash leather. The matter is of a mixture between green and gray, and in some instances where they occur in a very vascular area it is of a brick-dust color from the mingling of blood

with it. The slough is generally in an advanced stage of decomposition. Any attempts at removing it, resulting in its separation by piece-meal, and it gradually becomes detached from its base and elsewhere to which it is attached till finally it is discharged through the orifice which has formed, or been made. Generally after its separation and discharge it leaves a healthy granulating surface and the surrounding inflammatory thickening subsides, the parts gradually returning to their normal condition and leaving no other evidence of its former existence than a small scar and diminution in the thickness of the skin. The distinctive features between boils and carbuncles are wholly arbitrary; a boil being rather small, conical in shape, opening by a single orifice, and having a comparatively small slough, while a carbuncle is characterized only by its greater size, flatness, and especially by the formation of more than one orifice, with the formation of a considerable slough or superficial gangrene.

The cause of furuncles, like that of many other diseases, involves a problem that is rather difficult to solve; they frequently attend or follow itching, cutaneous diseases, as prurigo, eczema and scabies; are produced by irritant applications to the skin, or often follow the receipt of an injury, as a bruise; and finally they are undoubtedly produced by the continued breathing of impure air, long residence in moist places, or in a climate subject to sudden meteorological changes.

One of the earliest symptoms is an intense itching, which, if submitted to nature's means of allaying (scratching), results in a burning sensation, accompanied with slight pain and redness; later on, there is great tenderness with swelling and increased redness of surface, pain of a lancinating character, and occurring paroxysmally, with dull pain and a feeling of tension during the intervals; the lymphatic vessels and glands in the immediate vicinity, and in some instances for a considerable distance become red and painful, with more or less swelling of one or more glands.

There is generally some amount of febrile disturbance, which may increase to an alarming extent in the worst forms of the disease. The degree of prominence of the boil seems to depend on its situation and the depth of skin involved.

When superficial and involving the more lax tissues, the swelling is greatest, and when the inflammation sinks deeply in the more tense tissues, the swelling is less, although the mischief may be considerably greater.

The portion of skin destroyed, which constitutes the core, is the heart of the boil, and the object of the suppuration which follows seems to be the separation and expulsion of the core, the removal of which results in a subsidence of all inflammatory symptoms and a gradual return to a normal condition.

Notwithstanding the fact that several years ago the impression was very common that boils were conducive to health, a perusal of the literature on the treatment will readily convince any one that the supporters of this theory, as well as the majority of people, were very anxious to hit upon a means of exemption from their so-called salutary effects.

The treatment may be divided into constitutional and local. The constitutional must have for its object the regulation of any organ or secretion which has departed from the normal performance of its functions. If there is constipation, it should be relieved by a mild but effectual purgative, and nothing suits the purpose in my opinion more admirably than the administration of one-drachm doses of sulph. magnesia twice or thrice daily. This should be followed, if there are any indications of debility, with the mineral and vegetable tonics, as the following, to wit:

℞.	Quininæ sulph.,	gr. ij.
	Strychniæ sulph.,	gr. $\frac{1}{30}$.
	Ferri sulph.,	gr. $\frac{1}{4}$.
	Cupri sulph.,	gr. $\frac{1}{4}$.
	Ac. sulphurici arom.,	gtt. x.
M.	Sig.—Three times daily.	

Regimen and diet necessarily constitute a very important part of the treatment. The meals should be regular and wholesome, diet generous without containing any very stimulating properties, as I am of opinion that stimulants are very rarely, if ever, indicated in this trouble, and, furthermore, believe that in a majority of the cases the inflammatory process would be greatly aggravated by their use.

We all know that in most forms of inflammation unattended with marked symptoms of debility and exhaustion, stimulants oftener do harm than good.

I well remember the experience I had when quite small with an inflammatory ulcer on my leg, by drinking a glass of blackberry wine. The intense pain and resulting aggravation of all the inflammatory symptoms within an hour's time caused me to then and forever eschew the use of stimulants when the subject of any inflammation.

Brewers' yeast in ounce doses three times a day has some popularity as a curative agent. I have never given it a trial, but

from my own and the experience of others I am of the opinion that from four to twelve weeks with careful attention to the hygienic surroundings is the remedy *par excellence.*

The local treatment may be divided into abortive, palliative, and healing.

The abortive consists in the application of medicines calculated to prevent their development, and should be instituted at a very early period, otherwise it is useless. The remedies most relied upon in accomplishing this end are nit. of silver 10 to 20 grs. to the ounce of nitrous ether, carbolic acid from 33⅓ to 100 per cent. strength, compound tr. iodine or tr. camphor applied to the affected parts, stopping short of blistering, or even blistering. If this fails, which it in some instances does, then recourse is made to the palliative form, which consists in soothing the pain and hastening or promoting suppuration, and as poultices fulfil the two properties of heat and moisture, they are almost exclusively used. My objection to them and to the other forms of heat and moisture combined is that they have a tendency, if long continued, to soften and weaken the already debilitated skin, thus causing a larger slough to form, and rendering the parts more liable to the subsequent invasion of boils, a proof of which was clearly demonstrated to me in my own and another case that I closely observed. Having one on my neck, I poulticed it with the various materials in vogue till after the expulsion of the core, which involved a good deal of the skin. After its expulsion, instead of returning to its normal, the surrounding induration remained, and in the course of a few days I discovered that another boil was forming in the same indurated mass, and I afterwards had six situated on different parts of my body, for which I did nothing, with the result of not a single one rising the second time, besides their more speedy termination. The other case is so nearly the same as my own that I will not relate it. Consequently, if I should use the poultice at all, I would try to obviate those deleterious effects as much as possible, by limiting its extent and using some means of preventing the direct contact of any moisture to the skin by means of a layer of oiled lint or silk. If the pain is very great, some form of opium internally or a paste of gum opium locally may be used. The healing treatment consists in the adoption of such principles as will have a tendency to rid the boil of all irritation and assist toward a more speedy cure.

The skin must be kept clean and dry by means of tepid water and any of the medicated soaps, and after thoroughly drying it, if the tension and dryness is great, some of the soothing ointments of vaseline may afford temporary relief.

The broken summit should be dressed in such a manner as to keep a good-sized opening for the exit of pus, etc., and the dressing so applied as to keep the surrounding tissues free from the exudate.

I now come to the part of the treatment upon which there is a diversity of opinion, to wit., the use of the knife. It is my opinion that when a boil or carbuncle can be cured or allowed to go without the use of the knife, it will undoubtedly be an event most satisfactory to patient and physician. During the time that I was subjected to this trouble, I experimented upon myself by using the knife in the various stages on some, and allowing others to go untouched; and from the results obtained, I think I can safely say that the use of the knife at any stage before we are confident of the complete separation of the core by the suppurative process, is not only of no benefit, but has an undoubted tendency to prolong the inflammatory process, to say nothing of the pain attending the cutting. It has been urged by those who use the lancet that its use even before the formation of any pus relieves the congested vessels, yet we have all observed the sluggishness of the blood current and the rapidity with which these bleeding vessels become occluded by the formation of a clot, thus checking the hemorrhage and allowing the same vessels to very shortly become surcharged with blood and producing the same degree of congestion that formerly existed; and besides, we will all agree that the suppurative process is for the sole purpose of separating the core from the surrounding tissue, and thus aiding in its removal, and if we resort to the early use of the knife, we postpone this very important procedure, and if we use the lancet before a sufficient amount of pus has accumulated to accomplish its desired effect, we needlessly prolong nature's method (which in this instance is a good one) of effecting a cure by relieving the boil of its offending member.

CHLOROFORM vs. PARTURITION.

BY C. T. MELSHEIMER, M. D.,

Of Bluffton, Ind.

Since the discovery of chloroform in 1831 it has been utilized by the medical profession for the relief of the numerous ills that

assail frail humanity. In 1847, Drs. Simpson and Smith first administered it to mitigate the pangs of maternity, and, for the time being, its use became general, save with the exceptions of a few of the older obstetricians, who discarded its use. Since then, its administration has been greatly curtailed, not only in obstetrical, but also in surgical practice. The reason for this limitation in its use seems to be well founded on the fact that in parturition it weakens uterine efforts, prolongs labor in consequence, and thus lays the foundation for hemorrhage and other evils that threaten life. Its uncertain effects, which cannot be anticipated, must create some doubts in the mind of the surgeon whether its administration may not produce a paralysis of the heart, or some other evil, that might defeat the object of his operation.

Some time since Dr. B. W. Richardson made careful inquiries at the principal provincial hospitals of England for the purpose of determining the percentage of mortality by its use. He found 17,000 cases in which it had been administered without a single death. Yet subsequent experience in the same institutions presented a mortality of one death in 1250 cases. But he concluded that one death in 2000 or 2500 administrations would be nearer the truth, and says: "Even at this rate we have no remedial agent which approaches chloroform in point of danger." If it were not then for the danger that can not be determined, chloroform would be the anæsthetic par excellence in all traumatisms and all other afflictions requiring anæsthesia. Its warm sweetish taste, fragrant odor, prompt action, together with its almost freeness from creating gastric trouble, are so many advantages over its far less dangerous rival, ether. These seductive qualities are a great temptation for its use by dentists and surgeons in their minor operations, and no doubt with many fatal results if they were all reported. Every few days we have a death reported from its administration in some trivial operation in which its use was by no means justifiable, and yet are told by its advocates that there is but very little danger, if any, from its use in obstetrical practice when properly managed. How any special interference with the physiological law governing parturition offers a greater immunity from the evil results than other infringements, is a question I am not prepared to endorse. All philosophy teaches the contrary—a violation is followed by a certain effect; "there is no shuffling" in this matter, "the action lies in its true nature, and the penalty follows with unerring certainty."

The experience of many eminent physicians who are as well acquainted with its therapeutic effects and as competent to administer it in obstetrical practice as those who favor its use, denounce it entirely on account of its danger. Dr. Robert Lee says, that "it very manifestly slackens the uterine contractions, and in some cases puts a stop to them altogether." Dr. Rigby admits the fact, but claims it is of rare occurrence. "Spiegelberg asserts that no one has seen such effects when properly administered." Dr. Snow's observation in some cases led him to think that the very moderate use of chloroform diminished the strength of uterine contractions and their duration, and also prolonged the interval between them. Dr. McClintock, of Dublin, says it is "a most dangerous fallacy, and one that would invariably lead to disastrous consequences if generally acted upon." Dr. Robert Lee claims that its use is productive of exhaustion, hemorrhage, fever, inflammation, and cerebral disturbance. He published some seventeen cases of fatality in full up to 1854, and remarks: "Much reflection on the physiological effects and observation of the pathological mischief of chloroform leave no doubt on my mind that it ought to be altogether expelled from the practice of midwifery. There are no circumstances in which it can be with utility, none in which it can be with safety employed." Mr. Robert Johns, of Dublin, sustains Dr. Lee's opinion on this subject, and says: "I am firmly convinced that chloroform when inhaled during labor very fruitfully predisposes to hemorrhage, puerperal inflammation, chest affections, and other diseases detrimental to health and life, which it aggravates if given during their presence. It also lays the foundation of disease to arise at a more distant period, and thus increases the mortality in childbed and subsequent thereto."

Since then, multiplied arraignments could be adduced against its use, which are based upon solid facts derived from sad experience and not from speculative theories, that thus far have been not only a bane, but an obstacle in the way of medical progress.

As another victim of its proper or improper management, I report the following case that occurred here a short time since under its administration:

Mrs. B. S———, married, aged twenty-one years, primipara, stout and hearty—a picture of health—without a taint to mar a good history, felt symptoms of incipient labor between one and two o'clock a. m., September 5, 1886. Some nine hours afterward

chloroform was administered by the attending physician, and its action continued up to within a few hours of the completion of the second stage, which took place between eleven and twelve o'clock a. m., September 7. In consequence of placental retention it was again resorted to for the purpose of its removal; the result was a hemorrhage that proved fatal some nine hours afterwards.

In my criticisms of this case I am led to the conclusion that there was not the shadow of a pretext whatever for its administration, outside of a promise to mitigate the pangs of labor. As stated, she was in the enjoyment of good health; her antecedents together with her condition during the parturient stage, were as favorable as could be desired, and no doubt but her delivery would have been accomplished in safety and within a reasonable time had labor not been interfered with. I draw the following conclusions:

1. That the administration of chloroform in this case prolonged labor by decreasing uterine contractions and suspending the action of the abdominal muscles, which are great aids.

2. That its use had to be withdrawn a few hours before, to enable exhausted nature to recover a sufficient amount of strength for the completion of the delivery.

3. That the nervous system was so much affected by its prolonged use that it failed to meet the demand which safety required, and the result showed an inert condition of the womb wholly incapable of expelling the placenta.

4. That its administration in this most critical period for the alleged purpose of its removal was, in my opinion, without reason or judgment.

There is a certainty in this case, as well as in all others, that any infringement of a physical law is attended with some penalty instituted by Providence for a wise purpose. As a matter of admonition, pain forms a very prominent factor as a punishment, and it matters not how deeply we deplore its presence, or how anxious we are to be freed from its tortures, it is, in every sense, a symptom of mercy. In a pathological sense, it looms up out of the human wreck like a beacon to warn the patient, as well as the physician, of the gravity and locality of a disease that in its absence might prove fatal. So, too, in an obstetrical sense, it is the prime mover in nature's effort to accomplish a certain object, and when that is effected, its mission ceases.

Whatever mistakes, if any, Moses may have made in the genesis of mankind, there was none in recording the edict of Providence to Mother Eve that "in sorrow thou shalt bring forth children." Since then this ordinance has passed down the long line of generations, affecting, without any exception whatever, every mother. Why it should be so we cannot comprehend, and we should be willing, therefore, to leave this matter in the hands of Him who doeth all things well.

In this age of medical progress we are apt to ignore the efforts of nature by substituting some manipulative measures of our own, and the result has been greatly against us. In the use of the forceps alone, which was originally intended as an aid to nature under some very rare circumstances, we have extended the area of traumatic diseases of females by their untimely application. So much so, indeed, is this the case, that every important medical college in the world must have its chair on gynecology.

In looking over the fifth annual announcement of the College of Physicians and Surgeons of Chicago, I find the total clinical work for the year ending June 1, 1886, to be 23,430 cases treated. Of this number, there were 2,750 gynecological cases, making an average of one case to every eight and one-half cases of all others. Prof. Wm. S. Forbes, in his introductory lecture before the students of the Jefferson Medical College a short time since, reports 41 cases out of a total of 296 which were treated in one day by the twenty-six physicians who are daily employed in its charity. Here we have one case in a trifle over seven as the result of one day's labor by the professors of that famous institution. Of course, it is not presumable that this large number of cases are all due to our improved system of manipulation, but there is a strong presumption that a vast majority of them have their origin in meddlesome officiousness. In my younger professional life, some forty-three years past, wives brought forth stalwart sons and daughters with little or no aid from the physician or midwife. I can recall hundreds of instances in which the patient wife passed the ordeal of parturition without a murmur of complaint. What with perspiring and flushed face, a congested condition of the cephalic arteries, freighted with rich blood for the support of the nerve-cells while engaged in this additional duty, a long-smothered inspiration, with a push of the feet, and a pull of the hands, in fact nearly every voluntary muscle in the system was brought in harmony with the uterine efforts, a sharp and quick contest in favor

of the mother was mainly the result that left no evils in its wake to torture her future life as we so frequently see it now. We had but few procidentias, flexions, fistulæ, ruptures, and a host of other evils with which the logic of events is at present freighted. I will venture the assertion that the entire State of Indiana would not furnish a comfortable support to a professor of gynecology at that time. In our efforts to discover some specific for the cure of our multiplied ills, we have succeded in encumbering our materia medica with a lot of trash whose therapeutic effect in the main do not amount to so much straw. Occasionally, at long and rare intervals, a meritorious article is discovered that is of vast benefit, but the large majority is fit for nothing but to disappoint the hopes of the prescriber. What we need more than anything else at the present time is the conservatism of a Gross in surgery and that of a Flint in practice. If we have these acquirements, we need but few remedies to combat all the ills that are to be cured by medicine.

In our contest with disease we lose sight of the fact that the recuperative powers of nature are amply sufficient with a little aid to effect a restoration to health, and if this is tendered, she will respond kindly and be thankful for our services.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

Service of Dr. Longstreth.

Idiopathic Abscess of the Brain with Subnormal Temperature. Post-mortem Examination.

The patient was a girl, 13 years of age, admitted to the hospital only one week previous to her death. From what could be obtained of the family history, I will briefly state that she was one of three or four children, all of whom died in early infancy after brief illness, one in convulsions, another of marasmus, and so on. The patient herself as an infant was delicate, poorly nourished, and miserable, but seems to have done fairly well as she advanced in years. She had her hair cut off a short time since because of its dense thickness, and was supposed, as a consequence, to have taken cold. However, she complained of much and severe headache and loss of energy. She was described as extremely listless. Lost appetite and flesh. Her mother says she had a fit, which continued 2½ hours and left her in the same condition, but if anything the pain in head became more severe. We have, however, no good history of epilepsy.

She had no cough, no albumen, was constipated, her face was flushed and eyes red and injected, continued sleepy, but could be easily aroused, and would answer questions. The temperature was 100° F. on the morning of her admission. It fell toward evening, but rose the next day to same for a few hours, and then fell slightly below normal, and remained so till the morning of her death, when it rose to 100⅘°.

It looked somewhat like tubercular meningitis, but the history counteracted this supposition. Young children have this disease, but older ones do not, unless other organs show evidence of tubercular disease. And again, in inflammation of the brain there is always high temperature. The child could tell us little of herself, but we were certain there was pain throughout her illness.

I forgot to mention earlier that there was some protrusion of the eyeballs, which symptom, together with the constant pain, was evidence of pressure within the brain. There was also noticed some dilatation of the pupils; however they feebly responded to light, but failed if light continued any length of time. Later the left pupil became less responsive to the stimulus.

Ophthalmoscopic examination was made with great difficulty, and showed the arteries small, the veins large, and the retina pale, but no evidence of choked disk. More likely the trouble was seated upon the left side from the condition of the pupil, but there was no other evidence upon which to base diagnosis. Yesterday she died suddenly, and the autopsy explains the cause of her symptoms and sudden death.

A large abscess occupied the left post-cerebral hemisphere, causing the pressure and pain. Finally the pus penetrated the third, then the fourth ventricle, and of course the scene was suddenly brought to a close.

In all post-mortem examinations of the brain, the chief object is to see what is contained within the ventricles; the specimen should be handled with great care and skillfully dissected in order to avoid error. Here I will state that it is often of great value to bring to your aid the sense of smell in these examinations, *i. e.*, idiopathic brain abscess is quite odorless, while on the contrary traumatic abscess is very offensive.

In this case the abscess cavity extends over the greater portion of the left posterior lobe. Idiopathic abscess of the brain usu-

ally arises from thrombus; there is no evidence of this here. The point of special interest is how we have abscess of brain, extensive in area, and destroying much tissue, with a subnormal temperature.

Two Cases of Muscular Atrophy; Case 1 of Peripheral, Case 2 of Central Origin.

Case 1 is a hard-working woman of 45 years, who entered the hospital complaining of pain and stiffness in the left arm and neck, so severe she could scarcely move about, and only with increased suffering. Some two weeks before admission she was engaged in cleaning an out-house and took a heavy cold. This results in a rheumatic neuritis indicated by exquisitely painful points along the lines of nerves. Undoubtedly the sheaths of thick nerves are inflamed and injured, and the pain experienced by the patient is considerable. Here the indications for the internal administration of potass. iodid. were very clear, and the patient was placed upon it without delay. We also resorted to free blistering with some benefit. Pain in the brow developed later, in the region of the supra-orbital nerve. Iodine was at first used with but temporary good result. Potassium iodide is the most reliable aid we have at our command in these cases, and the results are generally satisfactory. This patient has been in the hospital two months, and altogether ill five months. There is therefore some atrophy of the muscles and contraction. The lesion in this case is *peripheral*, and if not promptly cured would result in permanent contraction. Hence we advise the daily application of the faradic current. This, in addition to the continued use of potass. iodid. in increased doses, will, in all probability, restore the patient to her original good health.

Case 2. Kate B., aged 32 years, has been in the hospital two months. I bring her before you to illustrate the marked degree of emaciation and loss of muscular power in this case of central trouble. Her family history is briefly as follows: Father died of apoplexy; mother died when patient was very young, cause of death not known. The patient had five children, all of whom died of convulsions in early infancy.

Eleven years ago patient had a fall, breaking a rib, which resulted in pleurisy. She had one continued fever. She states that she was never strong, but her general health was good, and she always worked very hard, was poor, and often underfed, and had but indifferent living throughout. She is absolutely without specific taint of any kind.

Four months ago she found herself rapidly losing strength, and was in a generally weak condition, and complains of rheumatism in shoulder and arm. The use of the arm in sewing produced sharp pains, shooting down to the fingers, and in two months it affected the left arm and neck. All this time she felt so weak that she inclined to lie down most of the time, was constantly losing flesh, and was pallid in the face. Following closely upon this, she began to suffer pain in the region of the heart, and shortness of breath. With this combination of ills, she was rendered helpless, and applied for admission to the hospital, in greatly emaciated condition. Physical examination revealed a distinct mitral murmur; also a soft irregular murmur at the aortic orifice, which however cannot be heard at the present time. Kidneys and lungs are in normal condition. Bowels are constipated, appetite poor. On admission she could not raise her right arm, and as her disease is advancing, she is now unable to lift either hand or raise her head from the pillow. She requires to be fed with a spoon like an infant. The pectoral muscles are included in the paralysis, which adds considerable to the poor woman's discomfort.

The slow progress of the disease and the fact that the patient was so abused by overwork, would incline me to think it a case of peripheral trouble; but close study, observation, and use of electricity disproves this supposition.

In cases of peripheral trouble so far advanced that "tapping" of the surface for macroscopical examination showed absolutely no muscular structure, the use of the battery recultivated the muscle fibre, so that the patient finally walked, and again "tapping" the surface showed a new growth of muscle.

This is a case of progressive muscular atrophy of central origin, and especially localized in a rare group. The prognosis is fatal, as respiration (owing to the atrophy of pectoral muscles) is becoming more and more difficult, and will finally cease.

CHARITY HOSPITAL, NEW YORK.

SERVICE OF JOHN J. REED, M. D.

Stricture of Œsophagus.

It sometimes happens that seemingly an easy case turns out to be anything but easy before the treatment terminates. Such a result is very liable to upset that confidence

which comes to a man who meets cases which happily yield to manipulation.

A man of 45 was seen in the ward suffering from difficulty in swallowing. He endeavored to sustain himself by carrying about with him a pocket full of bread crumbs, which he tried hard to swallow. He said that after a time they did go down, but it was neither a pleasant nor a profitable task to indulge in.

A bougie was introduced and met and overcame a stricture—a little below the pharynx—with that skill which has been referred to earlier in the article. The stricture was completely dilated, but strange to say there was little improvement.

A happy thought suggested another stricture several inches lower down. This also was met and overcome with marked benefit to the patient, and the usual amount of satisfaction to the medical attendant. It was thought best to continue the bougies, partly for the benefit of the patient, and partly for the benefit of those who wished to become familiar with the instrument.

After a week a powerfully disagreeable feature asserted itself, and that was that the bougie could not be prevailed upon to enter the lower stricture. Different sizes and different shapes were tried in vain. The man was still able to swallow a little, and it was thought that he might, if he took long enough time, swallow a small bougie, and thus relieve the surgeon of an irksome and depressing duty. He tried the suggestion but failed, and later on left the hospital, to the relief of those who had charge of him.

Apropos of the subject, a few remarks may be tacked on for the benefit of those who do not know much about stricture of the œsophagus. In the first place, the extent to which dilatation can be carried is from 18 to 20 millimetres, or about the size of a five-cent nickel.

Second, when you cannot get the sound to to engage or pass the stricture, shall you use force? Every man must settle that question for himself, keeping in mind some of the accidents which have happened. I may suggest two. One in the practice of a distinguished surgeon who during the manipulation caused the sound to rupture the œsophagus and enter the tissue of the lung. The case was unfortunate, as it resulted in death and an autopsy. Another case, a hospital one, when the sound entered an aortic aneurism. In the latter case an autopsy was not absolutely needed.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, October 7, 1886. The President, B. F. Baer, M. D., in the chair.

Ruptured Fallopian Pregnancy: Left Side.

Dr. Joseph Price exhibited the ovary and distended tube which had burst spontaneously. No fœtus was discovered; a very free hemorrhage into the peritoneal cavity had occurred. In the vast majority of cases the rupture is fatal. The cause of death is invariably hemorrhage.

Dr. Price also exhibited specimens from a case of

Double Pyo-salpinx, with Cyst of the Right Broad Ligament and Abscess of the Ovary of the Same Side.

The specimen consisted of both fallopian tubes and ovaries, and was a good example of pyo-salpinx, both tubes being closed at the ends and distended with pus. The right tube was long and very much distended, and with a large abscess of the ovary and a cyst of the ovary as large as a base ball, occupied the whole of the right side of the pelvic cavity, where the entire mass was firmly bound down and gave rise to great suffering.

The diagnosis in this class of cases is either made, or it is not made. He is quite sure Mr. Tait, before proceeding to an operation, is fairly certain of his diagnosis, and this generally presents but little difficulty. It is true that he operates early—as soon as he recognizes dangerous trouble. Dr. Price feels certain that delay with us is accountable for the large death-rate. Dr. Mundè says of Mr. Tait: "Now his wonderful dexterity and tactile sense come into play, for with these fingers he at once makes the diagnosis which he appears to pride himself on not attempting to make with accuracy in those cases demanding removal of the uterine appendages, the so-called 'Tait's operation,' except through the abdominal incision."

While at Birmingham, recently, he visited regularly his large public clinic, and watched carefully his rapid examination. He cited one case to illustratate the fact that Mr. Tait made his diagnosis through the vagina. After passing a number of cases, displacements, etc., which he did not think of sufficient importance to ask us to examine, he came to one, and kindly asked us to examine and express an opinion. Dr. Price examined and found the physical characterics of pus. Mr. T.'s reply was, "Quite right." The pa-

tient was at once sent to Spark Hill for operation. One tube was found full of pus, the other partially filled, and the ovaries cystic. This case illustrates that Tait does not guess at conditions and resort to abdominal section for diagnostic purposes. A world of mischief has already come of such statements. Of course there are exceptional cases demanding exploratory incision. Tait says, "save when the seat of such organic disease as will explain genuine suffering, the uterine appendages ought not to be removed," and that "those who attribute all the pelvic aches and ails of women to the ovaries and tubes and rush in to remove them, are dangerous people."

Dr. Longaker considered case 1 one of tubal pregnancy. Recurring attacks of peritonitis should direct attention to the probability of pyo-salpinx. The condition should be easily recognized, but is sometimes overlooked.

Dr. Howard H. Kelly remarked that in view of the increasing number of cases of hæmato-salpinx which we were now meeting, it was of the utmost importance that all those which came under our immediate notice should receive a more rigid examination, and elaborate attention should be paid to the clinical history. He believed positive diagnostic signs would be discovered which will make our interference more a matter of scientific certainty. Dr. Kelly was not speaking of those cases of a minor degree of tubal apoplexy or hemorrhage, symptomatic of a grave dyscrasia, but of those in which, owing either to the closure of an outlet or to disease of the mucous membrane of the tubes or grave local circulatory disturbance, a mass collected, forming a sausage-like tumor, producing various symptoms, some of which are common to pyo-salpinx. There is always great local tenderness, and often masses of exudate imbedding and obscuring the original tumor, and in cases of rupture often a peritonitis as rapidly fatal as in pus cases.

The suspicion that a tubal pregnancy lies at the bottom of the explanation in all these cases is negatived by the fact that a majority of the cases are hæmato-salpinx of both tubes.

A very important symptom which I learn was present in Dr. Price's case was also prominent in my own case; that is, a stillicidium of bloody grumous matter per uterus and vaginam, which is regarded by the patient as a prolonged menstrual period. This undoubtedly flows from the tube, and is altogether analogous to the free purulent discharge from the tubes of pyo-salpinx which he had seen. He intends in his next case of this kind to catheterize the tube and dilate and endeavor to relieve his case of hæmato- or pyo-salpinx in this way, if the discharge exists in sufficient quantity to lead him to suspect a patulous uterine orifice.

Cases of hæmato-salpinx resulting in rupture and death have been reported; one is figured by Winckel.

There are several facts in connection with the life history of pyo-salpinx which he would like to emphasize. In the first place, he has seen no case which was not the product of a gonorrhœal infection; and while not prepared to deny the possibility of a purulent change in the contents of a hydro-salpinx, for which Bandl contends, these cases so ably worked up by Dr. Price and his own observations elswhere all point to *gonorrhœa.*

Again, *these cases, with a history of such acute onset,* constant agonizing pain and constant high temperature and often typhoid condition, are the advance stages of florid gonorrhœa, and are found almost exclusively among the unmarried, and result from contact with a similar active gonorrhœa in the male. They form a picture utterly different from that developing from the exposure of a wife to the discharges of a husband who has been told that a trifling gleety discharge amounts to nothing, or who has long appeared well, only noticing the discharge after occasional debauches or unusual sexual indulgence. *Here the disease assumes the insidious sneaking type,* commencing with the little periodical pains scarcely noticed at first, a slight excess of menstrual flow with more pain after, and so on for months, until perhaps an abortion or a pregnancy completed seems to open up channels for a more serious and general infection. I have had typical cases of this in my own practice. It will be often noticeable here that in view of the much greater suffering experienced after the puerperal period, the patient will forget what has gone before, and blames her subsequent trouble on the mismanagement of the doctor.

The extreme importance of this whole question, second to none in the whole range of gynecological investigation, suggests to the mind many pertinent inquiries. What parts of the female genital tract are the favorite seats of the disease? In what order are the structures attacked? May it linger long in one part, and then under some change of condition attack another part? What is the resisting power of the virus to our various therapeutic agents?

The third question, he believes he can

answer satisfactorily. In addition to the well-known cases in which the disease lingers indefinitely in the urethral tubules and the vulvo-vaginal glands, *he believes that in many of our cases of pyo salpinx the disease has already lingered for a long time in the uterine mucosa, and has shown itself in the form of a uterine catarrh.* Since formulating this doctrine for himself, it has necessarily carried him back to the treatment of many of his cases by topical intra-uterine remedies, a form of treatment which he had some time since abandoned as irrational.

A patient is now coming to his office from whose pelvis he literally quarried out a large stinking tubo-ovarian pus sac. The left tube and ovary were unaffected, and he left them. She has a free purulent discharge from the uterus, for which the only rational treatment is active local measures.

It is important to recognize the fact that apart from a slight irritation of the outlets of the glands at the vulvar orifice, there may be no other signs of gonorrhœal disease than such discharge as issues from the uterus. The vagina may be perfectly sound. Braun and Schwartz lay especial emphasis on the fact that the flat epithelium of the vagina has great powers of resistance against the poison, while delicate epithelial structures, particularly the ciliated, are its favorite resting places.

We will apply our remedies with some success if we bear in mind the fact that the disease does not merely lie on the surface waiting to be wiped off to effect a cure, nor does it merely penetrate the tubular glands, but it invades the interior of the individual cells and attacks the nuclei; it penetrates the strata of connective tissue below, penetrates blood-vessels and lymph spaces, and forms thrombi. Relapses, then, even after the most energetic treatment, need not surprise us.

We find here, as in many other points, our forefathers did wiser than they knew; their therapeutic resources reached far beyond their knowledge of etiology. No wonder they used the most powerful acids and loved to leave a stick of solid nitrate of silver in the uterus to cure this most obstinate catarrh. If he cannot succeed in catheterizing some of these case, he knows of no other way in which a perceptible deposit of pus once formed in a tube can be removed but by the radical operation. And let there be no delay here. Cases have been lost simply from the secondary consequences of carrying around this bag of pus in the abdomen. Dr. Veit alone lost two cases from brown atrophy of the heart.

Dr. M. Price remarked that the good results in his brother's operations were due to free irrigation; from three to five gallons of warm water were used to cleanse the peritoneal cavity and to stream through it for ten or fifteen minutes.

Dr. Baer made some remarks upon the value of intra-uterine medication. Although high authorities had denounced it as unnecessary and dangerous, he had continued to use it; he has never given it up, as he has always found cases where it was needed; the method has been productive of good results in his hands, and he never expects to give it up. It will not cure pyo-salpinx, but may prevent it. It will be ludicrous to see the ultra-scientific return to intra-uterine medication after the denunciation to which it has been subjected. Dr. Baer prefers the injection of tincture of iodine, carbolic acid, nitric acid, or whatever application may be preferred, say about twenty minims, by means of a hard rubber syringe, to any of the cotton wrappers, or other forms of application. No case of inflammation has followed this method of treatment in his hands, and he has less uterine colic than with the application, perhaps because less force is required and no tenaculum or counter-pressure is necessary.

Dr. J. Price, in closing the discussion, remarked that in the first case there had been a missed period, and two or three weeks later a flow of blood commenced, and was continuous for weeks, with tenderness of the abdomen. By the microscope only can an exact diagnosis be made between hematosalpinx and tubal pregnancy, and he had had no opportunity to make an accurate one. Rupture may occur early in tubal pregnancy.

An unhealthy condition of the endometrium is very rare. The abortive treatment of gonorrhœa as applied to the male urethra has resulted in orchitis and stricture. The case of pyo-salpinx was operated upon four weeks after an abortion.

Dr. Drysdale, in view of recent strictures upon intra-uterine medication, would like to mention a case seen by him under Mr. Tait's treatment in 1883. The condition was endometritis, and Mr. Tait etherized the patient, dilated the uterus, and applied the Paquelin thermo-cautery thoroughly to the endometrium.

Dr. B. F. Baer presented the specimen, and related the following history of

A Case of Fibro-sarcomatous Tumor of the Ovary.

Mrs. ——, aged 36 years, married, two

children, youngest 15 years of age. About July, 1885, she first noticed that the lower portion of her abdomen was increasing in size, especially in the left iliac region, and she was troubled greatly with flatulent dyspepsia. She had suffered for many months before with pain in the left iliac region, and on November 29 she was seized with what she characterized as terrible pains in that region. She was compelled to take to her bed, and her physician said she had pelvic peritonitis. She remained in bed three weeks, when she became able to be up, still suffering considerable pain, however, with diarrhœa and an occasional discharge of blood from the rectum. She now noticed a hardness in the lower left iliac region. This continued to increase in size, while she grew weaker and began to lose flesh. At this time she passed into the care of another physician, who ordered her back to bed and blistered the surface of the abdomen. She remained in bed four weeks, but the growth failed to diminish in size; on the contrary, it continued to increase. On February 10 she was able to get up and began to feel stronger, but suffered from excessive tympany together with nausea, loss of appetite, and great pressure upon the rectum and bladder. She also suffered from severe dyspnœa.

On March 20, she was suddenly seized with cramp-like pains in the region of the tumor. These continued for a few days with almost entire absence of sleep and continuous nausea. The pain gradually subsided, but she was losing flesh and strength. She had another attack of pain, with such dyspnœa as to make her recovery a matter of doubt. Ten days later she first consulted me. On examination I found the abdomen greatly distended and tympanitic, except in the left hypogastric region, which was dull on percussion. Palpation revealed an irregular lobulated mass, apparently having pelvic connections. The uterus occupied the right anterior portion of the pelvis, crowded over by the mass in the left pelvic region. This mass was hard and firm and nodulated, extended into the hypogastric region, and was apparently closely connected with the uterus as well as with the other organs of the pelvis.

The previous history of the case, together with the physical signs now present, led me to suspect the presence of pus, possibly suppuration, in a thick-walled ovarian cyst. The uterus measured two and a half inches in depth. Its connection with the tumor did not seem more than ligamentous, and the apparent rapid development weighed against fibroid tumor of that organ.

The indications were plain. The patient entered my private hospital about April 29; ether was administered, and an exploratory incision was made. This revealed a nodulated mass having the color and appearance of a thick-walled ovarian cyst; but it seemed to be solid throughout, and was firmly fixed in the pelvis. Its size could not be reduced, and the incision was increased to six inches, the tumor separated from its adhesions, and lifted from its nest. I was much gratified to find that it had a very small pedicle, which was tied and the tumor was removed.

The patient bore the operation badly, and it was thought that she would succumb on the table. It was hours before the pulse could be felt at the wrist, but she rallied, and the next morning she seemed to be doing quite well. A free discharge of bloody serum had taken place through the drainage-tube. After alternate sinkings and rallyings, she died on the evening of the second day from shock, from which she had not entirely recovered since the operation. There was not the slightest evidence of inflammatory action. The discharge from the drainage-tube had ceased, and the wound was healing nicely.

This case is interesting on account of the character of the tumor. "A true fibrous tumor of the ovary is a thing of very rare occurrence," says Wells, and he goes on to say: "It will be found that many cases reported as ovarian fibroids are in reality tumors beginning in the uterus, which overgrow and involve the ovary so as to disguise its natural appearance or conceal it altogether." Doran says: "I have never found a solid ovarian tumor to be formed of pure fibrous tissue, and strongly suspect that fibroids of the ovary are identical pathologically with fibroids of the uterus. All the solid tumors that I have seen removed at operations have proved to be sarcomotous or cancerous."

Dr. Formad, who kindly examined this specimen for me, sent me the following report: "The solid tumor of the ovary showed, upon microscopical examination, to be a fibroma, with decided sarcomatous change—a fibro-sarcoma." A peculiarity of this tumor is its nodular character.

Dr. Kelly remarked that true fibroid of the ovary is very rare, and the specimen here presented is not, in his opinion, fibroid, but sarcoma. The only fibroid he has seen was one which he examined last spring. That tumor was about one centimeter in diameter, and although attached to the ovary, lay in the grasp of an adherent fimbriated extremity which cast some doubt upon the

origin of the small growth. The so-called fibroid appears to be in every way analogous to the "fibroids" of the uterus and broad ligaments, and a useful diagnostic expedient is the appearance of bundles of "sympathetically" enlarged fibres coursing from the hilum into the broad ligament.

Dr. Baer also presented the specimen and related the history of

A Mono-cyst of the Ovary.

Mrs. J., aged twenty-nine; married four years; sterile. Puberty at fourteen years of age, and menses always normal. Seven years ago she first discovered that the lower portion of her abdomen was increasing in size. This continued very slowly during the next three years, and at the time of her marriage it was large enough to be perceptible to her friends. It ceased growing until six months previous to the date at which she first consulted me, April 14, 1886, when she seemed to be in excellent health, no loss of flesh, no pain, complexion ruddy, and appetite good. Menstrual flow increased and accompanied with uterine tenesmus during the last two months, and she had begun to complain of pressure and over-distension. When the patient was in the dorsal position the abdomen did not flatten out, and it was symmetrical and smooth. Dullness on percussion over the anterior and lateral surfaces of the projecting portions of the abdomen, with resonance in the line of the colon. There was marked fluctuation in the dull region. Vaginal examination showed the uterus anteverted, of normal size, not freely movable, yet not closely adherent to the tumor.

Diagnosis.—Probably cyst of the broad ligament, from the long existence of the tumor, its slow growth, symmetrical development, together with the fact that it had not influenced the patient's health during its growth until it had attained such size as to interfere with respiration. Its removal was advised, and the operation was performed at my private hospital, April 27. An incision three inches in length was made. The tumor was rather darker in appearance than is usual in cysts of the broad ligament. It was now tapped, and a dark grumous fluid drained away. The tumor collapsed and was easily drawn through the incision, when its pedicle was found to consist of the entire broad ligament and to be very short, holding the base of the tumor deep in the pelvis. I was compelled to enucleate the cyst, leaving a broad open pedicle or surface, which I ligated *en masse*.

An accident now occurred from which the patient almost lost her life from hemorrhage, viz., slipping of the pedicle ligature. The mistake was in endeavoring to make a pedicle of the broad ligament, which had been laid widely open by the enucleation of the tumor, and which was not a proper pedicle. The mass was too great to be held by ligature, and was treated by bringing the edges together by interrupted sutures, of which ten were required. The hemorrhage was checked by grasping the vessels in clamp forceps until the sutures were placed. There were no after-symptoms. The patient is now entirely well.

I call attention to the monocystic character bf this tumor, its location in the broad ligament, and to the character of the contained fluid—dark-colored and thick, not clear and limpid as is usual in cyst of the broad ligament proper.

The report of Dr. Formad is: "The cyst is a monolocular one, developed from the ovary undoubtedly. Its lining is characteristic of ovarian cysts—epithelial; and whatever scrapings from the wall could be obtained showed the ovarian cells of Drysdale. The fluid was dark, grumous, and turbid, which excludes cysts of the broad ligament or par-ovarian, as the latter kind of cysts have always a limpid, clear liquid."

Dr. B. F. Baer also presented the specimen and read the history of

A Case of "Bursting Cyst of the Ovary."

Mrs. E. G. was sent to me by her physician, Dr. James Simpson. She was 47 years of age, and had been married 27 years, but had never been pregnant. Puberty at 14 years, menstruation always painful. She stated that twelve years ago she had felt a "lump" in the left iliac region. This was painful, especially during the menstrual period. In the fall of 1885 the lower portion of her abdomen began to enlarge, and within a few months it had so increased in size as to render locomotion and respiration difficult. On January 1, 1856, while riding in a street car, she was jolted in crossing a railroad track. She was at once seized with great pain in the abdomen, accompanied with pallor and faintness. She was taken home and placed in bed. A short time afterwards she began to vomit a fetid fluid, which came up in large quantity and at regular intervals, and at the same time she passed fluid of the same character from the bowels. The next day she had in addition attacks of profuse perspiration. She also had a slight metrorrhagia, the first evidence of menstrual flow since January, 1884. The abdomen rapidly diminished in size, and within a week had regained its normal dimensions. It was

three weeks before her strength had returned sufficiently to permit her to go about. She soon noticed that her abdomen was filling up again, and within a month it had become as large as it had been on January 1st. During the first week in March she was again seized with pain of the same character, and followed as before by vomiting, purging, diuresis and diaphoresis, and reduction of the abdominal distension. All of the symptoms were more marked in the second attack. Six weeks afterwards she was as large as ever, and she then came into my care.

She presented an appearance of great pallor and commencing emaciation, the "facies ovarian" becoming plainly perceptible. She was very nervous and excited for fear of a repetition of the phenomena that had occurred before.

On examination in the dorsal position the abdomen was rather projecting—not flat—and was larger on the right than on the left side. It was smooth throughout, and gave a dull sound on percussion over the whole anterior surface, resonance existing in the line of the colon. There was marked fluctuation throughout the dull portion. Vaginal touch showed the uterus to be situated high, as if it were drawn upward. It was not freely movable, and the external os too small to admit the sound.

Diagnosis. — Ovarian cystic disease; immediate operation advised.

On July 22d the operation was performed at my private hospital. Incision three inches, in median line; wall of the tumor thin and dark-colored. The trocar was passed and the contained fluid, dark in color, drained away. The cyst collapsed, and was easily drawn through the incision. The pedicle was short and broad, consisting of the broad ligament, and requiring enucleation of the tumor before its ligation could be accomplished. It was now found that another tumor existed on the left side. This had a peculiar shape, being elongated and deeply seated in the pelvis, as though it were entirely sub-peritoneal. The peritoneum extended out from the uterus, spreading over the tumor and approaching the abdominal wall, as is sometimes seen in a fibroid tumor of the uterus which has pushed that membrane upward in its growth. The cyst extended along the line of the colon, and at first I was not sure that it was not that organ greatly distended by gas. I soon determined that it contained fluid, and that its general appearance, color, etc., were similar to those of that just removed. It was emptied by means of the trocar, of a fluid similar to that of the first tumor, and the tumor collapsed. I hesitated as to the proper course now, because of the large and broad base of this cyst, and its close adhesion to the descending colon. I first thought of stitching it to the abdominal incision and inserting a drainage tube into it, and was soon afterwards sorry that I did not follow out my first idea. I began an attempt at enucleation, and this was attended by so much hemorrhage from the large surface which it was necessary to dissect that I was compelled to desist. I had separated at least six inches of the descending colon from the cyst, when I found that the latter dipped down so deeply into the pelvic excavation that I concluded it would be hazardous to finish the enucleation. I was in a quandary, for I had only two-thirds of the lining membrane of the cyst in my control, and I finally did what I was never compelled to do before, and what I may be criticised for doing in this case: I drew up as much of the cyst as was possible, threw a ligature around the mass, tied it as a bag, and cut away the external portion; thus leaving a large quantity of the lining membrane still within the pelvis. The oozing of blood from the large open surface was checked by ligatures and compression forceps until all bleeding had ceased. The toilette of the peritoneum was then made, a drainage tube inserted, and the incision closed. During the next few hours there was a free discharge of bloody serum through the tube, but by the next morning it had ceased. On the third day the tube was removed. The patient made an excellent recovery, and went home on the 23d day.

The points of interest in the case are: 1st, The bursting character of both of the cysts. 2d, Their monocystic character and probable ovarian origin. 3d, The deep attachment of the one on the left side, and its partial removal only.

"Bursting Cysts of the Abdominal Cavity" is the title of a very instructive paper which was read before the Gynecological Society in 1881, by Dr. Wm. Goodell, and in the paper and the discussion which followed, it was shown that this character of tumor is not so rare as the experience of a single individual might indicate. In addition to the cases which Dr. Goodell himself reported, three in number, there were no less than ten of the members present who had met with cases of similar character, some of the gentlemen as many as six or seven. Only two or three of the cases reported died as the result of the discharge of the fluid into the abdominal cavity. This appeared to prove that the

fluid of an ovarian cyst was not so irritating to the peritoneum as had been supposed. Dr. Goodell took the position that these cysts were of the broad ligament or parovarian, and not true ovarian cysts, and as a consequence the fluid was bland and unirritating, being readily absorbed and discharged through the emunctories. This view is probably correct for the majority of cases, but there are others where the evidence furnished by operation has proved the origin of the bursting cyst to have been in the ovary. The monocystic character of the tumors in this case, and their location beneath the peritoneum, within the folds of the broad ligament, would seem to indicate that they originated in the parovarium and not in the ovary; but the character of the fluid and its rapid secretion are in favor of an ovarian origin. An interesting feature in this case is the fact that the fluid was discharged by vomiting and purging, as well as through the bladder and skin, showing that it must have been emptied into the abdominal cavity as well as into the intestinal tract. From the close attachment of the tumor on the left side to the colon, it is probable that this cyst discharged itself into that organ, and was thus thrown off by vomiting and purging—while the fact that diuresis and diaphoresis took place at the same time in such quantity, and that the abdominal distension entirely disappeared, would lead to the conclusion that both cysts must have burst simultaneously, the one discharging into the bowel, the other into the peritoneal cavity. This is interesting if true, and probably unique; at least I have not been able to find a record of a similar case. I examined this patient recently, and found only a slight induration on the left side. She has been quite well.

Dr. Harris mentioned a case of bursting cyst that had been sent to Dr. Atlee for operation after the cyst had burst once and refilled. The day had been fixed for operation, but menstruation coming on a postponement was made, and the cyst again burst and the woman died in collapse. Ovarian tumor had been diagnosticated.

Dr. Parish reported a case of rupture of an ovarian cyst which occurred in the "old women's ward" at the Philadelphia Hospital. The rupture was spontaneous while the woman was in bed; she died in a few minutes from shock. In another instance in which rupture had not been suspected, one cyst, the contents of which were colloid, had burst, another ovarian cyst was found and removed. There was no evidence of acute inflammatory action.

Dr. Baer exhibited a

Fibroid Polypus of the Uterus.

The patient had suffered from metrorrhagia for two or three years. Labor-like pains were followed by spontaneous expulsion of the tumor, which was supposed by three physicians to be an inverted uterus; it was replaced in vagina and tamponed. Dr Baer found the uterus in normal position, and removed the tumor by means of the spoon-saw. W. H. H. Githens, M. D., *Sec'y.*

Castration in Mental and Nervous Diseases.

The October number of *The American Journal of the Medical Sciences* contains a symposium by the leading authorities on this subject in the United States, Great Britain, and on the Continent.

Sir Spencer Wells maintains that the operation of oöphorectomy, or the removal of normal ovaries, is one which may be advised in some cases of uterine fibroids, and in uncontrollable uterine hemorrhages. That it is to be resorted to in certain malformations of the genital organs, deformities of the pelvis, and accidental obstructions of the vagina. That the right to use it is very limited in cases of ovarian dysmenorrhœa or neuralgia, and only when they have resisted all treatment, and life or reason is endangered. That in nearly all cases of nervous excitement and madness it is inadmissible. That it should never be done without the consent of a sane patient, to whom its consequences have been explained. That the excision of morbid ovaries and appendages should be distinguished from oöphorectomy, and ought not to be done without the authority of consultation, as in most other cases of abdominal section. That in nymphomania and mental diseases it is, to say the least, unjustifiable.

Prof. Hegar holds that castration is indicated in a psychosis evoked or maintained by pathological alteration of the sexual organs, and in a neurosis originating from the same source, as soon as this imperils life or hinders all occupation and all enjoyment of life. The indication is also present when that disease represents only one casual factor in the genesis of the affection, without the removal of which a cure is not to be thought of. The remaining causes of suffering must be in this case accessible to treatment. Other milder methods of treatment must have been tried previously without success, or, as in the case of many small tumors of the ovaries and tubes, must from the outset give no promise of success. Castration must actually affect the cause which occasions or keeps up nervous irritation. The operation will thus be of use when a degenerated or dislocated ovary represents the irritative focus, or as soon as a greatly swollen and retroflexed uterus presses on the sexual plexus and the organ is brought into a state of atrophy. Castration promises success when the bleeding and anæmia occasioned by a fibroma play an important part in the maintenance of a psychosis, so that a cure does not appear possible without getting rid of that evil; but castration is absolutely no universal remedy for any neurosis originating from a genital-organ disorder, or kept up by the same. The cessation of ovulation will avail nothing if the irritation starts from the nerves which are compressed in a shrunken cicatrix of the broad ligament, or elsewhere in a cicatrix of the pelvic connective tissue.

Dr. Battey writes that he has performed castration for the relief of mental and nervous disorders, which may be divided into three classes: Oöphoro-mania, oöphoro-epilepsy, oöphoralgia. He uses the terms oöphoro-mania and oöphoro-epilepsy instead of hystero-mania and hystero-epilepsy, because clinical experience teaches him that these disorders are dependent upon a nervous irritation proceeding from the ovaries, and not from the uterus. He finds the disorders existing (*a*) in cases in which he recognizes organic disease of the ovaries, and is not able to recognize any organic disease of the uterus; (*b*) in cases of uterine as well as ovarian disease, when the diseased ovaries are removed, the nervous disturbance disappears notwithstanding the fact that a displaced or diseased uterus may remain. In his experience the time required for the disappearance of nervous disorders, after removal of the ovaries, has been quite variable. In general, epileptiform manifestations have ceased at once. Some of the cases have required for a time the tranquillizing effects of the bromides to ward off threatening symptoms, whilst others have needed nothing. His cases of mania have all been quite chronic, and the improvement has been slow. In oöphoralgia, in a few instances, the cure has been immediate and permanent. In the majority it has been slow and gradual; and in others nothing has been gained for even two years after the operation. In a few the long-established opium habit has proved a complete bar to recovery.

In his cases, which have had two years or more to test them, seven have been cases of oöphoro-mania—of them one was cured, and four improved; nine were cases of oöphoro-epilepsy, all cured; twenty were cases of oöphoralgia, and thirteen were cured and three improved.

Concerning Some Hypnotics.

Dr. S. G. Webber thus writes in the *Boston M. & S. Jour.*, October 14:

Several drugs have been lately given to the profession with the claim that they are valuable hypnotics. I have had an opportunity of testing these in the cases of many patients in the Adams' Nervine Asylum.

Paraldehyde has been some years in use. It has advantages over chloral. The immediate subsequent effects are less unpleasant. It vary rarely causes headache on the next day; sometimes patients have a sensation of fullness or pressure in the head for a few hours after waking. I gave it in one case where the patient had been taking chloral in large doses, not measuring the dose, and had been injuriously affected by the drug. The paraldehyde gave, in this instance, better and more prolonged rest; the patient partially recovered his mental powers and some measure of strength. The paraldehyde was continued several weeks in nightly doses of forty minims. In this patient there was probably disseminated sclerosis, and it did not seem possible to do without some agent to produce sleep, at least so long as he was at home.

The chief objection to paraldehyde is its disagreeable odor and taste, and also the odor it imparts to the breath. I do not remember to have met any unpleasant symptoms arising from its use; but had never seen a case in which it has been used habitually for a long time. The dose is from forty-eight to eighty or ninety minims; sixty minims is the average dose. Occasionally a dose of eighty minims has failed to give the sleep which I have desired to obtain.

Urethran came into notice later than paraldehyde; it is much more pleasant to administer, having scarcely any taste or odor.

When I first gave it the dose was too small, but by increasing it to thirty grains good results were generally obtained. Sometimes much larger doses are necessary. It is quite soluble; fifteen grains will dissolve in a drachm of water.

The after effects are generally unimportant. It has seemed once or twice to give rise to nausea the day after; but often the patient says the sleep has been very natural and refreshing. It is not so sure to produce sleep as paraldehyde.

Hydrobromate of hyoscin has the advantage of being almost tasteless; and the dose is small. I began with a dose of one hundred and twentieth of a grain, as recommended by the articles I had read; but soon found this too small, and increased to a sixtieth of a grain, using the following formula, giving twenty minims:

℞.	Hydrobromate hyoscin,	gr. j.	
	Alcohol,	ʒ iss.	
	Aquæ q. s. ut ft.	ʒ xx.	M.

In a few instances I have given twenty-five minims of this mixture.

There is so little taste to this that it can be given in some simple drink, as gruel or beef tea, without the knowledge of the patient.

In one patient it produced discomfort in the head the next day, so that after two trials it was given up and urethan given instead. In other cases the sixtieth of a grain given for a week or more has produced no bad effects. In a few cases it has failed to produce sleep, and the sleep secured in other cases has not been of so long duration as that usually produced by paraldehyde, but subsequently in these same cases the latter drug has not proved more efficacious. On the whole, my experience with this drug is that it will act favorably with a large number of patients, that it is acceptable on account of its lack of taste and odor, and because of its small dose; the sleep obtained is very refreshing and natural; it is, however, rather more likely to leave unpleasant effects, and seems to lose its power by repetition sooner than either urethan or paraldehyde.

Hypnone has a strong odor of bitter almonds. One patient spoke of its having "All the odors of Araby the blest." I have given it in capsules in dose of five to eight drops (.07 to .13) or even more; the former dose is rather small for good results. It will produce very natural sleep, and the patient awakes refreshed. It is of much less value than the drugs already considered, and fails more frequently than the others in producing sleep. It may be conveniently substituted for the others when they have been taken some time consecutively.

Dry Chloride of Sodium in the Treatment of Subinvolution of the Uterus.

Dr. Hal C. Wyman thus writes in the *Med. Age:*

That peculiar enlargement of the uterus, with its accompanying train of distressing symptoms, known as subinvolution of the uterus, is a matter of such common occurrence and is so often difficult to cure, that any one who has anything promising to offer, in the way of treatment, may be excused for enlarging existing literature on the subject. The writer desires here to commend most highly the surgical treatment of the disease.

The various plastic operations upon the uterine cervix which have been recommended by authorities he has found sufficient to compass a cure in the large majority of cases; but in those cases where for any reason operative surgical measures are withdrawn advisably, he has found the treatment by dry applications of sodium chloride to the swollen cervix most satisfactory. It has been in use in my practice for more than two years, and the success which has attended its use where I have applied it myself, or directed its use in consultation, has been most pleasing.

The formula I use is this:

℞.	Chloride of sodium,	ʒ j.
	Powd. slippery elm bark,	ʒ iij.
	Powd. hyoscyamus leaves,	ʒ j.

Mix and rub in a hot and dry mortar until thoroughly desiccated.

This is applied to a diseased cervix uteri in quantities equal to an ordinary teaspoonful once every other day, and sometimes oftener.

My common plan is to take a piece of absorbent cotton, circular, and three inches in diameter, just thick enough to hold the powder placed inside. The edges of the cotton are then folded over the powder and tied with a string, which is left of a length suitable to facilitate the withdrawal of the tampon thus made from the vagina. This insures the contact of the dry salt with the diseased uterus pretty nearly, although a thin layer of absorbent cotton intervenes between the salt to be dissolved and the uterus, to provide the fluid for dissolving it. In case the application proves painful, the tampon is withdrawn and another replaced containing a larger quantity of hyoscyamus or

opium, or morphine, as I may think best adapted to the case. To apply the chloride of sodium prepared in the manner just described, a speculum is first introduced and the swollen cervix brought into view and proper position, then that end of the cotton tampon which contains the chloride of sodium, etc., is passed through the speculum and placed against the cervix. It is held in position with dressing forceps, while the speculum is withdrawn. The tufted end of the tampon insures its contact with the cervix after the forceps are released.

The principle on which the influence of this remedy depends is found in:

(*a*) The depletion of the uterus of its fluid to liquefy the chloride of sodium.

(*b*) The antiseptic properties of the salt checking and preventing putrefactive and fermentative changes in the vagina and uterus.

(*c*) The presence of a mechanical support for the enlarged and malposed uterus favoring better circulation of blood through that organ.

In occasional cases I have observed that the patient did poorly when cotton was used to hold the powder in position—it appearing that the mere presence of the cotton adding to the bulk of the foreign body in the vagina was cause sufficient to make the patient listless and decline in health. In such cases I have introduced a small Ferguson speculum, brought the uterus into position, and thrown a teaspoonful of the powder directly upon the diseased organ. To relieve pain, I have added opium powder, hyoscyamus powder, or belladonna powder, to the salt and slippery elm.

The Indications of Resection in Gun-shot Wounds of Joints.

The following conclusions are given at the end of a paper by Dr. Schuchardt, of Metz, on "Indications at the Present Day on Articular Resections, both Primary and Secondary, after Gun-shot Injury" (*Deutsche Zeitschrift für Chirurgie*, Band xxiii., Heft 5 and 6):

1. The resections of joints that were performed for gun-shot injury before the era of antiseptic treatment gave very unsatisfactory results, with regard both to mortality and to the subsequent functional capacity of the limb.

2. Formerly primary resection gave better results than secondary resection with regard both to the recovery of the patient and to the restoration of the function of the injured limb.

3. In consequence of the bad results of articular resection in military practice, the most experienced army surgeons of former times were led to prefer an expectant or strictly conservative plan of treatment.

4. Since the introduction of the antiseptic method of dealing with open wounds, the indications for resection have become reduced, and the prospects of expectant treatment considerably improved.

5. Even when operative treatment is necessary, total resection of a joint is not indicated except when both articular surfaces have been injured over a considerable extent. In most cases of articular gun-shot injury, simple arthrotomy will suffice, the bullet and any osseous fragments being extracted, and joint washed out and drained.

6. Free exposure of the interior of the wound is not indicated, except in cases of very extensive injury of the soft parts and when the wound is dirty. The presence of a bullet or of any other foreign body in the joint does not necessitate a free primary incision into the articular cavity, when the wound is small and the external conditions are favorable. In most cases cure will be attained without any serious impairment of the function of the limb, by simple antiseptic occlusion.

7. Secondary resection is indicated when expectant treatment has not had the desired result, and should be practiced without delay whenever the wound presents an abnormal appearance, and the healing process has been interrupted.

8. The duration of treatment in aseptic cases is a little shorter after primary than after secondary resection; but the difference is not of such a degree as to justify rejection of conservative or expectant treatment on the field of battle.

9. Theoretically the dangers of a fatal result are less in the primary than in the secondary operation. A comparison in this respect, however, is not quite fair, as the secondary resection is performed only when expectant treatment has failed; and to every single case of secondary resection there are many cases that have been treated successfully by antiseptic occlusion.

10. The functional results depend in the first place on the amount of bone that has been removed, and, in the second place, on the kind of after-treatment.

11. In the knee and ankle, ankylosis, or even a stump after amputation, is to be preferred to a movable joint.

12. Transportation is more unfavorable to the patient after resection than after expectant

treatment. For this reason and that of the large number of wounded after any important engagement, and also of the difficulty of performing under such conditions an aseptic subperiosteal resection, it is necessary to avoid, if possible, any recourse on the field to operations of this kind.

The Blue Discoloration of the Vaginal Entrance as a Diagnostic Sign of Pregnancy.

Before the American Gynecological Society Dr. James R. Chadwick, of Boston, said that he had made it a point in all cases of early pregnancy to make a note of how much discoloration he could detect; he had tables of four hundred and forty cases examined. He had divided the discolorations into four groups: First, doubtful, where it was so faint that he could not be certain of its presence; Second, suggestive, where it was more marked; Third, characteristic, where the discoloration, though faint, is confined to the anterior wall of the vagina and more particularly to the urethra, just below the meatus and on either side of the meatus. In every instance where this was present the woman was pregnant, with one exception; and Fourth, marked, where the congestion has become deep and exhibits the appearance constantly seen during pregnancy.

He did not claim that the characteristic discoloration is seen in every case, but if carefully looked for, it would be found quite pronounced in the majority of cases. The color varies from a violet to a dark, dusky, almost black color. He claimed that this sign was of especial value in cases of retroversion where the size of the uterus could not be determined, and in extra-uterine pregnancy. He had obtained much assistance from it in a few cases of pregnancy accompanied by fibroid tumors, and also where there was a large accumulation of abdominal fat. When present, this sign is of decided value in the early months of pregnancy, but its absence should not be accepted as a positive proof against pregnancy. Cases were cited in which the discoloration had been observed in the seventh or eighth week of pregnancy.

DISCUSSION.

Dr. H. P. C. Wilson, of Baltimore: "I consider this one of the most valuable means of diagnosticating pregnancy in the early stages. It is invaluable in cases where women wish to deceive you."

Dr. A. J. C. Skene, of Brooklyn: "This has seemed to me to be a most reliable sign in the early months of pregnancy. I believe that it is an illustration of the physiological hyperæmia of the formative stage of development."

Dr. Joseph Taber Johnson, of Washington: "Some years ago I referred to this point, and the discussion which followed seemed to indicate that the discoloration was a congestion produced by interference with the return of the venous circulation by the pressure of the enlarged uterus. It was held that the same discoloration could be produced by any other tumor which would have the same effect as the pregnant uterus."

Dr. William H. Parrish, of Philadelphia: "In regard to the continuance of the discoloration after labor, I have noted that in primiparæ where involution of the vagina takes place completely, the discoloration disappears with corresponding rapidity. Where there is sub-involution, the blueness may continue for a longer time. In multiparous women where the blueness was marked, I have associated it with a condition of sub-involution of the vagina."

Dr. James R. Chadwick, of Boston: "I have failed to notice any persistence in the discoloration described. The general discoloration may persist, but this characteristic blueness will, I think, be found to disappear. I have looked for this sign in forty or fifty cases of fibroid tumor, and have not found it in a single instance."

On a Case of Purpura Hemorrhagica.

Dr. John Madden thus writes in the *Physician and Surgeon:*

A. J. H., aged twenty-seven, American, unmarried, and a carpenter by trade.

First saw patient August 4. He is a strong muscular man, has always been in excellent health; parents, brothers, and sisters all alive, and free from any trace of hereditary disease. About a week before consulting me, patient noticed a small "blood-blister" upon his lower lip. Thinking that it was caused by smoking, he abandoned his customary indulgence. Successively there appeared ecchymoses and blisters upon the hands, arms, and mucous membrane of the mouth. An examination of the oral cavity disclosed the presence of numerous pin-head to split-pea sized blood-blisters upon the inside of the lips, the buccal mucous membrane, the tongue, tonsils, and posterior wall of the pharynx. The extravasations upon the extremities took the form of ecchymoses, varying in size from minute specks to that of a silver half dollar, many of which were characteristically colored by age.

The urine was large in quantity and bloody. Amount secreted from 10 p. m. to 10 a. m. ten ounces, fifteen or twenty per cent. of which was blood. A microscopical examination showed a large number of unaltered blood corpuscles, but no free hæmoglobin casts nor epithelium debris. The following prescription was given:

℞.	Ergotine,	ʒjss.
	Sulphate of iron, exc.,	grs. xlv.
	Sulphate of quinine.	grs. xxx.

Misce et ft. pil. number thirty.
Sig.—One t. i. d.

August 6. Amount of blood in urine much less.

August 7. Amount of blood diminished to a trace.

August 8. Blood in urine entirely gone.

Patient is now apparently in perfect health. During the whole course of the disease the patient complained only of feeling "a little weak," and having some slight pains in the region of the kidneys. There was no temperature changes and the digestive functions were unimpaired.

Syzygium Jambolanum in Glycosuria.

Dr. C. C. Kingsbury thus writes in the *Med. Age:*

During the month of June last, I was called to see Mrs. McF——, multipara, æt. 54. Her case was somewhat obscure, owing to her reticence, and being a very energetic business woman, she had kept going as long as possible.

In examining her urine I was interested in its peculiar color and odor, and proceeded to test for sugar. On inquiry I found that for some two years she had been treated for "kidney trouble," and had taken a good many kinds of medicine. Taking an ounce of recently voided urine, I found it contained between thirty-five and forty grains of sugar. I treated her to the best of my ability with such remedies as are usually laid down in our books as indicated in diabetes, until August 24. On that day I succeeded in getting and preparing for her an infusion of syzygium jambolanum, one-fourth ounce to the pint of water. Dose, one teaspoonful three times per day, gradually increased to two tablespoonfuls four times per day.

On the 27th of August her urine showed fifteen grains of sugar. I have not had an opportunity of making a test since, but am to-day (September 6) in receipt of a letter from the lady's daughter in which she reports continued and rapid improvement in her mother's condition.

During a practice of thirty-five years I have seen many such cases go down to the grave under the treatment of skillful, honest, and earnest men, and was thus led to try a new method in this case. I did not follow any of the prescribed rules as to diet, but told my patient to eat any kinds of food that she relished and that agreed with her.

The improvement which so promptly followed will, I am sure, convince any one of the wisdom of giving the new treatment a trial in this class of cases.

The Danger of Syncope in Hot Baths.

It is surprising, says the *Lancet* (July 3), that deaths by syncope during the use of hot baths are not more common than the coroner's court returns would show them to be. The peril of faintness by the mere determination of blood to the surface of the body, thus quickly depriving the heart of its usual normal support and stimulus, is very great. In cases of muscular weakness of the heart this danger must be imminent whenever the "hot" or even the "warm" bath is used. Apart from this obvious risk, however, there is always the possibility that in weakly or too impressionable states of the nervous system the peripheral stimulation produced by the application of heat to the whole of the cutaneous extremities of the afferent nerves may so act on the centres as to arrest the evolution of energy by an inhibitory influence. It is doubtful whether we lay enough stress on this consideration when prescribing the use of such external agents as act on large areas of surface and strongly impress the nerves there commencing. We know how burns of even moderate severity may kill by the impression they produce on the centres of vitality from the periphery. There is much to learn in regard to the nature and extent of the central effects which may be thus caused. Whether for good or evil, the application of heat or cold to the whole surface is a potent measure, and one that ought not to be recklessly resorted to, more especially in cases of great susceptibility, involving such excitability of the nervous centres as often co-exists with fairly good health in a weakly body.

Balsam of Copaiba in Gonorrhœal Ophthalmia.

Dr. S. Haynes, of Saranac, N. Y., writes to the *Medical Record* that he was called to see an infant, four days old, who was suffering from conjunctivitis, contracted from the mother, who had gonorrhœa at the time.

The inflammation had existed two days, and the cornea was found covered with thick pus, and the eyelids were so swollen that they could be separated with difficulty even when the child was under the influence of chloroform. For several days the remedies used seemed only to hold the disease in check, and the infant meanwhile was rapidly losing flesh. Severe stomatitis was also developed. Applications were now made of balsam of copaiba to the temples, the external surface of the lids, and above the eyebrows, three times a day, a little being occasionally inserted between the lids. The pus was carefully removed every hour by pledgets of cotton, wet with solutions of alum or sulphate of zinc, and fresh butter was applied to the edges of the lids every night. From the commencement of the use of the balsam a marked improvement was noticed, and in three or four weeks the cornea was perfectly clear and free from disease, and the child had gained in flesh. The case had everything against it, as the parents lived six miles away and could be visited only occasionally, the mother was confined to bed for a great part of the time, and the family were ignorant and suffered from the want of many of the necessaries of life.

Reviews and Book Notices.

BOOK NOTICES.

A Manual of Obstetrics. By A. F. A. King, M. D. Third edition. Pp. 178. Philadelphia: Lea Brothers.

This convenient little volume has received a careful revision at the hands of its author, and now appears with succinct notices of all that is new in its branch, added to that which has received the stamp of long experience. In its present shape we know of no compendium of the art of midwifery which is superior to it.

House-Plants as Sanitary Agents; or the Relation of Growing Vegetation to Health and Disease. By J. M. Anders, M. D. Pp. 335. J. B. Lippincott & Co. 1886.

The thesis which the author has at heart to prove is that the presence of growing plants in a house is beneficial to its human inhabitants; and that forests and vegetation in general should be considered as active depurative and sanitary agents. This he shows by a chemical discussion of the processes of vegetable life, by examples of the prophylactic character of plants, and by maintaining that sufferers from some diseases, notably pulmonary consumption, have been benefited by this means.

This essay shows a wide range of reading, and presents a number of striking facts which will not be found collected elsewhere. It eminently deserves the careful perusal both of physicians and of that large class of the intelligent public who are beginning to think and act for themselves on the all-important questions of personal and national hygiene.

How to Strengthen the Memory; or, Natural and Scientific Methods of Never Forgetting. By M. L. Holbrook, M. D. Price $1.00. New York: M. L. Holbrook & Co. For sale by Lippincott & Co.

The faculty of memory is so indispensable to be retained unimpaired and as strong as possible, that the purpose of this volume must be lauded as a worthy one. There is not in it much that is new; but it reiterates and repeats with good tact of selection much that has been suggested in this direction.

The secret of the whole matter is *association*, intelligently carried out and persistently applied. How its details are to be managed are well told, and any reader who is dissatisfied with his retentive powers, and is willing to work real hard to improve them, can do so by following the plans here laid down.

The Curability of Insanity. A Series of Studies. By Pliny Earle, A. M., M. D., etc. Pp. 284. Philadelphia, J. B. Lippincott & Co., 1886.

The title of this book would have been more correct to have read, "The Incurability of Insanity." At least the net result of the author's "Studies" is to persuade him, and, we think, on very good grounds, that the percentage of recoveries reported from asylums, especially American asylums, is delusive, and that as we obtain more trustworthy figures we learn that fewer and fewer cases really get well.

The author's analysis of statistics and his criticisms on asylum reports are keen and convincing, and his volume should be carefully conned by every alienist.

—The Board of Health of Buffalo is about to enforce the law recently made, requiring the licensing of "baby farms." This industry will in the future be placed under the auspices of the sanitary police, and it is to be hoped infanticide from want of care and starvation, now so common in "baby farms," will be suppressed.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

PHYSICIANS AS EXPERTS IN CASES OF ASSAULT.

Several cases have recently occurred in our immediate vicinity where the ordinary practicing physician has been called upon to give testimony as to whether an assault had been perpetrated upon a woman immediately antecedent to her murder. In one case, at least, the physician's affirmative evidence caused the jury to convict a human being of murder in the first degree. Upon what this physician based his evidence, the papers did not say; but we feel that the question is such a grave one that a few words of warning are necessary.

Ordinarily, the condition of the hymen is accepted as evidence of the virginity, or otherwise, of the woman. But this is an antiquated and exploded idea that is of no earthly use. It has been demonstrated by careful physicians that a complete uterine examination can be made without the slightest laceration of the hymen, and as it might happen that the male organ was small or the hymen scanty and tough and resistant, we must conclude that its presence is not conclusive proof of virginity. So much for one side of the question. But suppose we find the hymen ruptured; is this conclusive proof that intercourse has taken place? By no means; for masturbation would be just as likely to produce this result as would intercourse.

Let us suppose that a woman is found dead, and it is supposed that she was murdered. It is also supposed that she was assaulted just prior to her death. A physician is called, he makes an examination, finds a *fresh* rent in the hymen, and on this evidence gives it as his opinion that intercourse has recently taken place. From what we have said, it will be readily seen upon what an unstable foundation such an opinion must rest.

But have we any sure means of concluding whether an assault has been made? Yes; if the act has been completed. Let the physician who is called to such a case as we have supposed, at once procure some of the vaginal fluid and subject it to microscopical examination. If he finds spermatozoa, he can swear that an assult has been made; if he does not, he cannot. The only instances where this crucial test could fail would be in those exceptional cases (mentioned by Goodell) where the semen is devoid of spermatozoa. If suspicion of assault is strong and if it strongly points to a particular man, additional evidence of very great value may be derived by a microscopi-

cal examination of the semen of the suspected man, that is to say in those cases where spermatozoa are not found in the vaginal secretion.

The burden of what we have to say is that the physician who swears that an assault has been made in any case where he has not found spermatozoa in the vaginal fluid, swears to an uncertainty, and he may thus be the means of condemning an innocent man to the gallows.

CANCER OF THE SPLEEN.

Dr. Notta (*Arch. gén de Méd.*, 1886, p. 166) reports the following rare case: A boy, æt. 7, thus far in good health, was suddenly taken sick without any detectable cause with hæmaturia, which continued without interruption for about three days. Notwithstanding a good appetite, the boy remained pale and weak after the accident. A few weeks later he began to complain of lancinating pains in the left abdominal region. On examination, the existence of a splenic tumor was demonstrated, which occupied the whole left side of the abdomen and reached below to the iliac fossa and extended over the papillary line. The tumor was hard, smooth, not painful. Liver was enlarged; lymphatics not swollen, no fluid in the abdomen. Notwithstanding proper medication (sojourn in the country, quinine, cold water-affusions), the emaciation progressed more and more rapidly, mild fever set in, the liver became larger and irregular in outline, nausea and vomiting occurred, and two months after the hæmaturia the boy died.

The post-mortem examination showed cancer of the spleen as primary cause; later the liver became co-affected. The disease always seems to begin with pain in the splenic region, which, however, radiates towards the left shoulder or over the whole left side. The organ is not sensitive at the beginning, but later becomes so. The other symptoms depend upon the rapidly increasing enlargement of the spleen, the co-affection of other organs, especially the liver, and upon the general cachexia, not due to malaria, syphilis or leucocythæmia.

ACUTE RHEUMATISM WITH PECULIAR COMPLICATIONS.

That we are not yet acquainted with all the varied complications which may accompany inflammatory articular rheumatism, the following cases, reported by Dr. Grimm, *Deutsche Milit. Ærzt. Ztsch.*, '86, H. 12, proves.

A sergeant, æt. 28, was taken sick with an acute rheumatic polyarthritis, which twice relapsed and slowly progressed. When it had disappeared without fever or heart-complication, the most peculiar choreic movements set in, so severe that patient could scarcely remain in bed and protect himself against accidents. At the same time psychical disturbances were noted, as: laziness in thinking, pseudo-idiotism, then hallucinations of hearing and sight and stupor. Under treatment with bromide of potash the patient completely recovered four weeks later. G. ascribes the trouble to inanition and the formation of emboli, caused by the micro-organisms of acute rheumatism.

In a second case, also that of a sergeant, æt. 27, in the second week while the rheumatic symptoms suddenly vanished, the following pernicious phenomena set in: furibund delirium, collapse, coma, hyperpyretic temperature (112° F. during the last fifteen minutes before death and increasing one degree after death).

According to Grimm the rheumatic microbes suddenly greatly multiplied and emigrated into the blood-vessels of the brain, a view which seems the more probable, as we have similar occurrences, for instance in lobar pneumonia, when complicated with brain-symptoms.

KŒNIG'S FLEXION-CONTRACTURE.

Not long since Kœnig discovered a flexion-contracture, which he observed in certain organic lesions of the brain. E. Bull (*Berl. Kl. Woch.*, 1886, 47,) now reports two cases in whom the phenomenon was observed in the knee-joints; when the thighs of the patients were flexed the knees could not be extended, while the contracture of the latter at once ceased, as soon as the hip-joints were extended. In the one case the patient suffered with a tumor cerebelli, while in the second a thrombus, due to caries of the petrous portion, had formed in the transverse sinus.

While Kœnig seemed to consider the symptoms in question as characteristic of lesions of the pia, Bull believes it to be present in every case of augmented intra-cranial pressure, therefore also in compression of the brain. It is certain that it always indicates a lesion of the brain, but of diagnostic value it would probably be only when appearing earlier than other symptoms.

For the purpose of avoiding mistakes, Bull also directs our attention to the fact that even under normal conditions a perfect

extension of the knee is only possible when the angle between abdomen and thigh is greater than 90°.

Notes and Comments.

Rupture of the Appendix Vermiformis.

S. E. Bryant, male, 45 years of age, came under the observation of Dr. T. H. Briggs (*Med. Age*) on the evening of the 10th of September last. He found him suffering great pain, and had been for the thirty-six preceding hours. A diagnosis of biliary calculus had been made. On the morning of the 11th he found him free from pain. Temperature 96°; pulse 100; hands and feet cold. On the 13th death occurred from what he concluded to be shock, resulting from rupture of the gall-bladder or ductus communis choledochus. The temperature did not rise above 96° after he was called. During the last fifteen years he had suffered more or less each year from very acute pain, which usually left him in a few days.

Autopsy thirty hours after death. On exposing the liver, its bladder and ducts were found perfect in every respect, with no evidence that there had ever been any trouble with them. Quite an extreme effusion of the liquid contents of the bowels was found in the peritoneal cavity. The appendix vermiformis may be a cause of extreme pain during a period of years. Can such a condition be determined during life, and would we not be warranted in surgical interference?

Parenchymatous Injections of Quinine in Ague Cake.

Professor F. Fazio relates in the *Rivista Clinica e Therapeutica* for July, 1886, the case of a woman, thirty years of age, who had suffered from malarial fever, and who had also marked hypertrophy of the spleen. The tumor extended from behind the margin of the ribs to a line drawn on a level with the anterior superior spine of the ilium. It was determined to attempt a reduction in the size of the spleen by means of parenchymatous injections of quinine. The instrument used was the ordinary hypodermic syringe provided with a longer and thicker needle than usual. The bisulphate of quinine was employed, and thirty-two injections of each 4½ grains were made, care being taken to make the successive punctures at some distance from each other. The result of treatment was a reduction of over one inch in the length of the tumor. The injections were not followed by pain, or by any other unpleasant symptoms. The experiment was interrupted by the departure of the patient from the hospital, but Dr. Fazio believed that the results obtained were sufficiently encouraging to warrant further trials of the method.

The Diagnosis of Ascites.

Dr. Tripier, of Lyons, publishes an article in the *Lyons Medical* on the means of diagnosing ascites by the vagina. He was led to try this method accidentally. He was attending a young woman for tuberculous pleurisy, and had occasion to examine the uterus. The situation of the os was normal, but when the fingers touched it, it seemed to fly from it by reason of an abnormal mobility. A certain amount of liquid was supposed to be present in the cavity of the pelvis, and thus caused the phenomenon. The patient died, and the autopsy confirmed the suspicion entertained during life. Several times subsequently he had recourse to this method, and found it of great utility. He was able to diagnose the presence of liquid at the very commencement of peritonitis or of cirrhosis, in heart disease, at an early date. Besides, he recognized that every time there was œdema over the sacrum and the lower part of the body, there was water in the abdomen, and when the inside of the thighs was the seat of the œdema. The importance, as regards the treatment, of this method is obvious.

Imperfectly and Ill-Shapen Jaws.

In *Items of Interest*, Dr. M. H. Cryer says:

Diseases of the soft parts often change the shape of bones, particularly in the young. Aggravated tonsillitis in childhood will, if chronic and accompanied by hypertrophy, cause the roof of the mouth to take an inverted V-form. If the patient has suffered from the disease on one side only, that side will be pulled down. This is caused by the extra tension of the palato-glossus and palato-pharyngeus muscles. Then the palatal process of the upper maxilla and palate bones are prevented from forming the normal dome-shaped roof of the mouth, and the vomer is directed or pushed from its proper position, becoming crooked or lacking space to occupy its normal position, it is deflected or pushed forward, thus forming an abnormally large nose. By proper treatment at an early period many such deformities can be avoided.

Tumors of the maxillary sinus may change the shape of one or more of the surfaces of the upper maxilla; and aneurism or other soft tumor constantly pressing against a bone will cause its absorption.

Method of Inducing Labor.

Prof. Tibone (*L'Union Medicale*) suggests a modification of the method of Krause, which is, as is known, the introduction of an ordinary sound into the uterus, leaving it there until labor is established. Tibone's method is as follows: After taking all antiseptic precautions, the cervix is brought into view by means of a speculum and then a special kind of sound is introduced. The author prefers the plain English bougie, No. 10 or 12. The bougie is held a moment in a warm mercurial solution and is gradually softened: it is then introduced into the cervix, and slowly and gradually pushed up until it has entirely disappeared inside the womb. There is then placed upon the mouth of the womb a large tampon of cotton soaked in an antiseptic solution; the patient may then get up and keep about until the appearance of labor. This method is perhaps a trifle slow, but is sure, and on account of the softness of the instrument used there is no exposure to violent rupture of the membranes or to serious injury to the placenta. The author has used this method repeatedly, and always with satisfaction.

A Case of Voluntary Starvation.

Dr. A. Voelkel, in the *Deutsche Medicinische Wochenschrift*, No. 31, 1886, reports the case of an old toper, of a very obstinate disposition, to whom the landlords finally refused to supply any more liquor. The man said then that he would live no longer, went to bed, and refused to take any food. He lived for twenty-four days, taking nothing but a little water and brandy. He died in a deep stupor, without convulsions. At the autopsy the body was found not to be greatly emaciated, a considerable layer of fat still remaining on the chest and abdomen. The stomach and intestines were filled with gas, but the intestines were otherwise entirely empty, and the stomach contained only about three ounces of a brownish fluid, the walls of both stomach and intestines being very thin and pale. The kidneys were normal, but rather soft; the bladder was empty. The spleen was very small, the liver fatty, and the gall-bladder was filled with about an ounce of thick brown bile. The heart was small, fatty, degenerated, and empty; the lungs contained air, but were dry on section. All the organs were very anæmic.

What Is It?

Under the above heading a correspondent, M. C., sends to the *Medical Record* the report of the case of "a gentleman forty years of age, who, for the last six years, has practically been disabled from walking by a sensation of 'throbbing' accompanied by a peculiar and intense feeling of weakness in both insteps—greatly aggravated by exercise, and virtually prohibiting locomotion. No swelling or change of external appearance has ever been noticed. The condition of hyperæsthesia or tenderness exists over a surface of about one inch and a half by one inch. When touched, the feeling is of a dull blow, but not that of injury to a nerve. Burning sensations were formerly much noticed, but never in both feet the same day. It hurts to go more than one step at a time in descending stairs. For the first three years the suffering was extreme and intensely annoying, constantly attracting his attention, although never interfering with sleep. During the last three years a gradual improvement has been taking place. The original cause is believed to have been a few days' wearing of tight boots."

Alexander's Operation.

Dr. Doléris contributes a lengthy article on this subject to the *Nouvelles Archives d'Obstetrique et de Gynecologie* (January to May inclusive). After reviewing at length the history of the operation, which he clearly shows was first suggested by Alquié in 1840, he cites Alexander's cases in full, and adds to these 100 others which he has collected in literature. To these should be added nine more operations by Dr. Polk, of this city, three by Dr. J. B. Hunter (not reported), and two by Dr. F. B. Harrington, of Boston. Several others have been performed in this city, so that the number of actual operations is probably 175 at the lowest estimate. In spite of the evidence thus adduced, there is a singular feeling of uncertainty among gynecologists with regard to the ultimate value of the operation. Its technique requires no further exposition. As regards the *permanence* of the results we are still left very much in the dark.

Prevention of Miscarriage.

Dr. W. J. Strother reports (*Gaillard's Medical Journal*) the case of a married wo-

man, thirty years old, who had had six or seven miscarriages, these generally occurring from the third to the fifth month. Hemorrhage would begin about the second month, and recur every four days until the fœtus was expelled. At the last miscarriage Dr. Strother was in attendance, and remembering having read of a case of abortion reported as being due to fatty degeneration of the placenta, in which tincture of chloride of iron and chlorate of potassium were employed with success in the succeeding pregnancy, he examined the placenta and found it almost one mass of fat. At the beginning of the patient's next pregnancy, therefore, he ordered a mixture of tincture chloride of iron, ʒiij, and chlorate of potassium, ʒiij, in water, ℥vj, of which a teaspoonful was given three times a day. She took this regularly almost every day until she was delivered, at full term, of a healthy male child. About the third month she had a slight "show," but the hemorrhage never returned.

Oophoraphy.

Under this name, Dr. Imlach described before the British Gynecological Society a novel operation for the permanent reposition of prolapsed ovaries, when their extirpation by laparotomy is undesirable. In multiparæ, according to this gentleman, the ovaries are kept in place by the infundibulopelvic ligaments; whenever the latter become much relaxed, the ovary sinks downwards and becomes congested by reason of the interruption of the circulation in the vessels supplying the organ. Dr. Imlach seeks to restore the prolapsed ovary to its normal position in the pelvis and to maintain it there by shortening the relaxed infundibulo-pelvic ligament and suturing it to the hilum. Fourteen successful cases were reported. In the discussion which followed the paper Mr. Lawson Tait insisted that prolapsed ovaries were usually the seat of chronic inflammation, and therefore that the operation suggested by Dr. Imlach might relieve but would never cure the patient.

Castration in the Treatment of Cavernous Myo-Fibromata of the Uterus.

Dr. Goldenberg lays particular stress upon the application of the so-called "Hegar's operation" to cases of uterine fibroids in which the tumor is recognized as a soft interstitial growth, with a rich vascular supply. In this class of tumors the entire uterus is diseased, and hemorrhage is a prominent and dangerous symptom, because of the excessive congestion which attends each menstrual period. The writer believes that production of the premature menopause as well as a marked decrease in the size of the tumor, are results more invariably obtained when the fibroid is of the soft or cavernous variety, than when it is hard and less intimately connected with the uterus. The size of the tumor as well as the age and general condition of the patient do not affect the value of the operation.

Warts.

The *Med. Press*, October 20, says:

It is fairly established that the common wart, which is so unsightly and often so proliferous on the hands and face, can be easily removed by small doses of sulphate of magnesia taken internally. M. Colrat, of Lyons, has drawn attention to this extraordinary fact. Several children treated with three-grain doses of Epsom salts, morning and evening, were promptly cured. M. Aubert cites the case of a woman whose face was disfigured by these excrescences, and who was cured in a month by a drachm and a half of magnesia taken daily. Another medical man reports a case of very large warts which disappeared in a fortnight from the daily administration of ten grains of the salts.

Death Following an Intra-Uterine Injection.

Dr. Otto Engström reports in the *Finska Läkaresällskapets Handlingar*, Nos. 5 and 6, vol. 27, the case of a woman, thirty-seven years of age, who was suffering from fungous endometritis. The mucous membrane of the uterus was curetted and then an injection was made of a solution of iodine, one part to thirty of water. After the second injection, which was made with a stronger solution (1 to 10), the patient had a chill which was followed by symptoms of peritonitis, and death occurred three days later. There was no evidence at the autopsy of any fluid having passed through the Fallopian tubes, and the writer believed that the inflammation of the peritoneum arose by extension from the uterine substance.

Conservative Ovariotomy.

Professor Schroeder has recently devised an ingenious operation, which consists of excising the diseased portion of an ovary and leaving the healthy tissue, with a view to the preservation of the function of the organ. After carefully dissecting out the larger cysts, Prof. Schroeder unites the

raw surfaces with fine sutures, and then restores the ovary to the abdominal cavity. According to the experience of this celebrated surgeon, and of those who have practiced this operation, the results have been most gratifying. While menstruation continued, the former dysmennorrhœa was relieved in several instances. In one case the patient became pregnant after excision of portions of both ovaries.

The Uses of Creasote.

Creasote is the subject of a very interesting paper in *La France Médicale.* After treating of its history and chemical nature, its therapeutics as an antiseptic, parasiticide, and caustic are enumerated, and several formulæ are given, from which the following are taken:

℞. Creasote, 1 part.
Water, 100 parts.
M. Ft. sol. As a wash for ulcers.

℞. Creasote, 1 part.
Lard, 15 parts.
M. Ft. ungt. An ointment for fetid ulcers.

℞. Creasote, 3 drops.
Water, 90 grammes.
Orange-flower water, 30 grammes.
Essence of citron, 2 drops.
M. Ft. mist. A teaspoonful every two hours, in typhoid fever.

℞. Creasote, 1 part.
Cod-liver oil, 150 parts.
M. Ft. mist. A teaspoonful daily in phthisis.

Condurango in Gastric Catarrh.

Condurango bark was introduced a few years since as a specific for cancer, and, like many other much-vaunted remedies soon fell into oblivion. Dr. E. Suñer, however, has lately used it a good deal in cancer of the stomach, and in gastric catarrh. He gives one tablespoonful of the infusion every two hours. In all cases of cancer it relieved the pain, increased the appetite, and improved the digestion. In gastric catarrh its good effects were very evident; the appetite and digestive powers improved, and the nausea and sickness ceased; the general tone of the system at the same time improved, and the hypochondriacal symptoms disappeared.

The Wanderings of a Needle in the Body.

The Paris correspondent of the *Medical Press and Circular* relates a case occurring in the practice of Dr. Delaire, of a girl who accidentally swallowed a large stocking needle. At first she did not suffer much, but in a few hours she felt great pain in the epigastrium, and soon afterward in the lower part of the abdomen. She thought she was going to die. Frequent desire to micturate was subsequently felt, and drops of blood were passed. At last, at midnight, fifteen hours after the accident, she felt, after a violent effort, something sticking her at the vulva. She put her hand down and drew out the needle; her suffering was immediately at an end.

Fish as an Invalid Diet.

In the *Lancet*, August, 1886, Mr Nairne gives a series of cases in which a fish diet has given rise to very serious mischief. Several cases are related in which convalescents from typhoid fever have met with a fatal relapse after partaking of some boiled fish. For some time the author excluded fish from invalid diet, as he thought it the cause of all the mischief. Lately, however, he has found that if fish be steamed it is more tender, and can be eaten with impunity.

Popliteal Aneurism in an Ataxic Subject Cured by Pressure.

Dr. Longhurst, of London, reports this case (*Med. Press and Circular*): Patient, æt. 51. An Esmarch's bandage was applied to the limb for an hour and a half; then a screw tourniquet to the femoral, and so on during the day. Pressure was omitted at night. A shot bag weighing 11¼ pounds was tried instead of the tourniquet, and this treatment was pursued for the next two days. On the evening of the third day no pulsation was visible. The pulsation did not return.

Nitrite of Amyl in Cocaine Poisoning.

Schilling reports a case of poisoning by the injection into the gums of two drops of a twenty per cent. solution of cocaine. Amaurosis, deafness, and complete loss of motion and sensation occurred. Regarding the phenomena as due to cerebral anæmia consequent upon the contraction of the blood-vessels, he caused the patient to inhale nitrite of amyl, by which she was rapidly relieved.

Nævus.

Dr. W. J. Beatty (*Brit. Med. Jour.*) has cured eight cases of nævus, perfectly and painlessly, by painting the affected spot night and morning with liquor arsenicalus until ulceration took place. A cure is effected in from three to five weeks.

How to Administer Cod-liver Oil to Infants.

Dr. Yeldham (*Med. Record*, October 2,) says, let the nurse dip the end of her finger in the oil and put it in the child's mouth, and it will be sucked off with avidity and pleasure. This may be repeated five or six times in the twenty-four hours. He says it never disagrees with the child, and can be given to the youngest infant often with great advantage.

Grineviski's Ointment for Acute Rheumatism.

℞.	Oil of hyoscyamus,	℥j.
	Mercurial ointment,	℥ij.
	Extract of aconite,	℥j.

Correspondence.

Singultus Successfully Treated by Hypodermic Injections of Apomorphia.

Eds. Med. and Surg. Reporter:

J. V——, aged forty-five years, shoemaker, weight about 240 pounds, a user of morphia to a limited extent (about gr. jss. daily), called me to stop his hiccough, which had continued nearly three days. I tried mustard, camphor, nitro-glycerine, bromide, chloral, by the mouth; I tried electricity to the phrenic nerve, and inhalations of nitrite of amyl; I tried hypodermics of morphia (gr. ss.), and morphia and atropia, and pilocarpine (gr. ⅓), but nothing brought relief for any length of time until apomorphia was used hypodermically, and in repeated doses, beginning with one-tenth and increasing to one-fifth. In order to make the vomiting as easy as possible, I gave a glass of milk or water soon after the injection. The relief would come as soon as free emesis occurred, and last from three to eighteen hours, when it would have to be repeated. A final cure was effected with the fourth injection.

I report this case, as I find so little in my books in regard to this trouble, *Napheys' Medical Ther., Bartholow's Practice, and Ringer's Mat. Med.* being the only books at my disposal that mention this ailment.

W. W. Fletcher, M. D.

Susquehanna, Pa.

News and Miscellany.

Why We Have Two Eyes and Two Ears.

Dr. Williams, in the *St. Louis M. and S. Jour.*, says:

"To give the body an evenly-balanced and symmetrical appearance is not the only reason why it is provided with an eye and an ear on each side. It is true that the body is composed of two apparently exactly similar halves, but the internal organism does not carry out the idea suggested by external appearances. The true reason for the duplication of the organs of vision and hearing lies in the physical nature of light and air, and of things around us, and thus two eyes and two ears become a necessity for the comfort and convenience of living beings. Two eyes are necessary for us to be able to judge of the distance of objects, and two ears to comprehend the direction from which sound comes. Any one who has suddenly lost the sight of one eye or the hearing of an ear can fully appreciate this fact. When such a person desires to take hold of or pick up a small object, a pin, for instance, he will most frequently overreach it or fall short of it, and he will wonder why this should be the case. The explanation is very simple, and is based upon the same principle that enables a surveyor to run off a base line and, by measuring the angles made by vision to a distant, perhaps inaccessible, point, tell the exact distance to that point. In ordinary vision the base line is the distance between the eyes. The eyes being directed towards a point, vision proceeds in a direct line from each, the lines crossing each other at the point looked at, thus making a triangulation, as it were, the base line of which is the distance between the centres of vision in each eye. The calculation of distances is to a certain extent a reflex mental action; but to a certain extent only, since it is a faculty which can be cultivated to a very high degree.

"The reason why two ears are necessary is much more obvious to the casual observer of natural phenomena. Sound travels by waves radiating from a central point of disturbance, like the wavelets caused by dropping a pebble into still water. So far as the hearing of each individual is concerned, these waves move in a direct line from the cause of sound to his ear, the impact being greatest in the ear that is nearest to the source.

"The effect, in this respect, of the total loss of hearing in one ear was forcibly illustrated by the statement of a patient who consulted me recently. He lived in a wild portion of Tennessee, and spent a good deal of his spare time in the woods, hunting squirrels, accompanied only by his dog. An explosion suddenly destroyed the hearing in one ear. After this accident, while in the

woods, he found that he could hear his dog bark, but for the life of him he could not locate the direction of the sound, even when quite close to him, and he was compelled to take his little boy along with him to find the dog. After a time persons learn to correct, to a limited extent, the errors in estimating distances, after the loss of vision, but the effect of the loss of an ear upon the estimation of the direction of sound is never corrected."

An Example for Other Doctors to Follow.

An amusing story is told of two practitioners in a small town in England who held radically opposite views concerning the hygienic management of typhoid fever. While Dr. A. closed all the windows in his patients' rooms, so as to obviate the slightest danger of a chill, Dr. B. held that fresh air was absolutely necessary. An epidemic broke out In the neighborhood, and each doctor regulated the ventilation of his patients' rooms on his own theory. There were often in one street patients belonging to each doctor. A walk down the street sufficed to point out the houses where each had patients. Where Dr. A. had a patient the windows were all closed; where Dr. B. had one they were all open. Nevertheless, the doctors were very good friends and agreed to differ. Dr A., if asked whether he did not consider Dr. B.'s plan of opening all the windows very bad practice, would reply that it was all very well for Dr. B. to do so, but that it it did not do for him (Dr. A.) to adopt the plan. At last Dr. B. fell ill himself with the fever, and sent for his colleague to attend him. "There, now," said every one, "there's a patient who won't shut his windows for Dr. A.—Dr. B. won't, I'm sure." However, on visiting his patient, Dr. A. quietly ordered all the windows closed, and closed they were during Dr. B.'s illness. When the latter was reproached for abandoning his theory in his own case, he said: "Well, it didn't do for his own patients to have all their windows shut, but it did for Dr. A.'s patients, and he was one of the latter, and must act accordingly."

This story is vouched for by a correspondent as having been of actual occurrence.

Sam Jones to Women.

The Rev. Sam Jones preached a sermon to over one thousand women in Indianapolis, in which he said: "Never help the devil to lay your husband in a drunkard's grave. The hardest thing that I can say, and I say it in all kindness, is that the biggest fool God ever looked at is a wife who stirs a toddy for her husband. Sisters, let me warn you by every drunken husband, father, and son in the land, that he became so by taking drams, and many of them by drinking toddies stirred by their wives. You go home and empty out every one of those closets. I'll tell you another thing; there are plenty of women who drink lager beer. My, my, my! Did you hear what brother Price said about beer the other day? He said that it agreed with the Dutch stomach, but that it didn't agree with the human stomach. The idea of women drinking lager beer! Why, if you would take some of that stuff and put it in your hog-trough, and didn't sweeten it or anything, there isn't a poor, half-starved hog in the lot that would touch it. [Laughter.] If you did deceive some poor hog into drinking it, as soon as he got sober, he would leave this town, and you couldn't drive him back. I've heard women say that they drink beer for their health. When my wife and children can't live without drinking beer, I am ready to preach their funeral sermon. Do you hear that? I say the only hope for America to-day is in the fact that we have sober mothers and wives, and if the women should be debauched into drinking like the men do, we would soon become a nation of helpless drunkards."

A Victim of Cocaine.

A prominent physician of Pittsburgh has become a victim of the cocaine habit. Recently he became very violent, and, under the delusion that he was attacked by burglars, drew a revolver and began firing indiscriminately right and left. Other occupants of the house were awakened and rushed into the room, whereupon the doctor leaped through a rear window and took refuge in an outhouse. It was with the greatest difficulty that he was made to understand that he was not pursued by burglars, and he then returned to his office. A physician was sent for, who, detecting a couple of red spots on his arm, asked to be allowed to look at them. Quick as a flash the sleeve was rolled down, and the patient positively refused to grant the physician's request. He was then taken to the Central Station and a search of his rooms instituted. A bottle of cocaine, from which half of the contents had been used, and a syringe, were found.

This is the first serious case developed in this city from the use of cocaine. The habit

had so grown on the doctor that he constantly kept the drug about him. About a week previously, he had a frenzied attack and sent for a physician, who, becoming frightened at the sight of a revolver in his hands, was compelled to send for assistance before he could apply a remedy.

Midwifery Statistics in Vienna.

Dr. Karl Braun has just published some very valuable statistics showing the improved and improving safety with which the patients in the first obstetrical clinic in the Vienna General Hospital have been delivered during several years past. He took charge in 1857, and during the twenty-six years following, *i. e.*, to 1883—108,889 women have been confined in this clinic, which, it may be remarked, is only one out of three obstetric clinics in the hospital. Of these 1945 died, making the average death-rate for the whole period 17 per 1,000. During the first six years there were 722 deaths out of 25,123 cases, *i. e.*, 28 per 1,000. The ventilation and warming arrangements were then altered in accordance with modern sanitary views, and various other hygienic improvements made, the result being that there was a decrease in the mortality during the next sixteen years, 1117 deaths occurring in 68,770 cases, or 16 per 1,000. Since 1881 there has been a further decrease, owing to the use of antiseptics, etc., 15,000 cases in the last five years having resulted in only 106 deaths, or 7 per 1,000. This improvement appears to be still continuing, as during 1883 the mortality was only 2 per 1,000. During the whole period 7964 students received practical instruction in the clinics, the average number in each session or semester being 136.

A Question of Sex.

A curious case came before a London magistrate a few days since in the person of a lad charged with theft. It transpired, however, that the lad was of the female persuasion, and had donned male attire simply because as such work was easy to find, whereas arrayed in her own more ample garments starvation stared her in the face. The incident is more comic than serious, but it bears on one of the burning questions of the day, female labor. It is certainly rather strange, only that custom has made us blind to the fact that for exactly similar work a woman is paid less than one-half the wages paid to a man, and it is not easy to furnish a plausible explanation of the fact. It is this, combined with a perfectly comprehensible dislike to domestic service, which in many instances is little better than slavery, that drives so many girls on the streets. Life "on the streets," as girls soon find out to their cost, is the vilest and most exacting of slaveries, but the discovery is only made when it is too late to withdraw, and is persisted in under penalty of having nothing to do and nothing to eat.

A Remarkable Mother.

A Boston physician was called out of a sound slumber the other night to answer the telephone. "Hello! what is it?" he asked, little pleased at the idea of leaving his comfortable bed. "Baby is crying, doctor; what shall I do?" came across the wire. "Oh! perhaps it's a pin," suggested the doctor, recognizing the voice of a young mother, one of his patients. "No," was the reply. "I'm sure it can't be that." "Perhaps he has the colic," returned the doctor, with well-simulated solicitude. "No, I don't think so," replied the anxious mother; "he doesn't act that way." "Well, then, perhaps he is hungry," said the doctor, as a last resort. "Oh! I'll see," came across the wire; and then all was still. The doctor went back to bed and was soon asleep again. About half an hour afterward he was again awakened by the violent ringing of the telephone bell. Jumping out of bed and placing the receiver to his ear, he was cheered by the following message: "You are right, doctor; baby was hungry."—*Chicago Living Church.*

Clinical Society of Maryland.

At a meeting of the Clinical Society of Maryland, held October 1, the following officers were elected to serve for the ensuing year:

President.—Dr. Randolph Winslow.
Vice-President.—Dr. S. T. Earle.
Recording Secretary.—Dr. A. C. Abbott.
Corresponding Secretary.—Dr. W. J. Jones.
Treasurer.—Dr. R. W. Johnston.
Executive Committee.—Drs. J. W. Chambers, H. Harlan, and B. B. Browne.

The reports of officers and committees showed a very healthy condition of the Society, the treasury having an ample surplus for current expenses, and the membership of the Society having increased to 190 active members. The Society meets on the first and third Fridays of each month at 8:30 p. m., in the hall of the Medical and Chirurgical Faculty of Maryland, northwest corner of St. Paul and Saratoga streets.

How the Therapeutic Value of Our Mineral Springs may be Increased.

Dr. Clarence C. Rice thus concludes a paper in the *N. Y. Med. Jour.:*

1. Physicians, individually or in committee, should make careful analyses of our mineral waters.

2. The medicinal value of the waters should be tested by clinical investigation, and the conclusions arrived at given to the profession.

3. If the waters are found to possess marked medicinal merit, physicians should interest themselves in the development of the springs and the improvement of bath-houses and apparatus.

4. Physicians, in sending patients to a mineral spring, should be most careful to select the proper water, and should send with the patient his history and the diagnosis of his disease for the benefit of the physician at the bath.

5. Patients at our mineral spas should be placed under more rigid medical discipline, and more attention should be paid to their habits of living.

6. The social life at our watering-places should be placed on a more wholesome basis.

He Didn't Advertise.

"Good morning, gentlemen," said the doctor, as he walked into the newspaper office, "is the city editor in? Ah, yes, I see. Mr. Huntemup, there was an accident on Fremont avenue this afternoon that I thought you would like to hear of. Mrs. John Peduncle was thrown out of her carriage and sustained a compound fracture of the right clavicle. She was taken home and medical aid summoned. Her injuries were skillfully attended to, and she is now resting easily. You might say that I was called, and have charge of the case."

"By the way, doctor," said the advertising manager, looking up from his books, "I would like to insert an advertisement for you in the *Banner*. I'll let you have it a year for $30 an inch, payable—"

"Sir," interrupted the doctor with a scowl, "I never advertise. It is contrary to medical ethics. Good day, gentlemen."

The Johns Hopkins Endowment.

The *Baltimore Sun*, of October 7th, publishes a statement of the financial resources of the Johns Hopkins University. For the year ending August 31, 1886, the income was $225,922.38. The total expenses for the year were $185,020.96; leaving a balance of $40,901.42. Among the receipts $17,804.12 were credited to tuition. Among the expenses $126,828.26 are charged to salaries. The University own 15,057 shares of B. & O. Railroad stocks, valued at $2,195,400. The remainder of its endowment fund is invested in bonds, stocks, mortgages, real estate, buildings, apparatus, etc. The total endowment is $4,359,350.43. In addition the University owns the Clifton estate of 280 acres, which is valued at $2,000 per acre, making the property of the University worth to-day about $5,000,000.

How they Practice in India.

An Indian physician was holding forth the other day to some of his brothers of the craft in England. "You sairs in the West," he said, "do not understand the practice of medicine. In my country, if a rajah with nothing of sickness sends for me, I go and I say, 'Sair, your case is a bad one; you will be worse before you are better.' I give him some medicine, and I go away. The next day I go again, and I find him heaving like a sea-sick mandarin, and wishing that the son of his mother had never seen the light. 'Sair,' I say, 'I told you so; you have passed a great crisis. There is no more need of medicine. Another sun will see your cure complete.' I then collect my fees, and I go away. When I have cured a few more rajahs, I shall come again to your country and take a villa on your little river Thames, with the green turf sloping down to the waterside."

The International Medical Congress.

In the remarks made by Dr. N. S. Davis at a recent meeting of the Chicago Medical Society, he gave an account of the cordial reception with which he and his fellow-representatives of the organization of the Congress had met in Great Britain, and of the assurance they had received that the European profession would be well represented at Washington. He closed with this statement: "In France they do not pay the slightest attention to any differences we have, and, just as far as they imagine there is coldness in England or Germany, the Frenchman comes with the more enthusiasm to make it up."

She Won't Pay for Paper.

Lady customer enters a pharmacy and asks for fourpenceworth of bismuth and twopenceworth of magnesia, requesting them to be mixed and divided into twelve powders.

While the powders are being put up she regales herself with a whiff of all the smelling bottles and perfumes within her reach. When the packet is handed to her she lays down a shilling, out of which the compounder takes eightpence. Lady customer (lifting change): "How much are you charging me?" Chemist: "Eightpence." Lady customer: "But I only asked for sixpennyworth." Chemist: "True; but there are the papers, and the time taken up in ——" Lady customer (interrupting) "Oh, but I shall keep the papers carefully and bring them back to you." The chemist's reply has not been recorded.

An Interesting Monument.

M. Clermont-Ganneau has communicated to the Academy of Inscriptions and Belles-Lettres a note relative to a discovery made by him in an old building at Jerusalem. It was a block of stone, with a Greek inscription signifying that any stranger who should have passed that limit would be condemned to death. It is evidently a fragment of one of the posts which formed, in the temple built by Herod, a dividing line between the exterior inclosure of the Gentiles and the inner precinct reserved for the Jews. It will be remembered that St. Paul barely escaped stoning when he was accused of having introduced Greeks into the inner circle with himself. The stone has been removed to Constantinople, but a cast has been taken, which will be preserved in the Museum of the Louvre.

College of Physicians of Philadelphia.

At the meeting of the College, held on Wednesday evening, November 3, Dr. Oscar H. Allis read a paper entitled "Man's Aptitude for Labor in the Erect Position, with an Inquiry into the Agencies that Predispose to a General Preference for the Right Leg and Arm;" Dr. Thomas B. Reed describes a plan for a Children's Ward at the Presbyterian Hospital; Dr. Charles W. Dulles read "A Note on a Case of Anencephalous Monster;" Dr. Thomas J. Mays, "A Study of Pulmonary Consumption in Philadelphia;" and Dr. Francis Dercum presented some interesting clinical specimens from a case of lead poisoning.

A Case of Infinite Grit.

Some months ago the *National Car-Builder* mentioned that a prominent western railroad company, having instituted an inspection of all the train-men for the detection of color-blindness, it was found that one of the oldest passenger-engineers could not read or write. The result of this discovery was, that the man was taken off the road at once, and notified that he could have a switch engine to run. Instead of accepting this oblique promotion, he asked and received leave of absence for three months. Then he went home, got the assistance of a teacher, and began laboring to acquire a knowledge of reading and writing. This was done so vigorously that at the expiration of his leave he wrote a very respectably-penned letter to the master mechanic, intimating that he was ready to take his engine.

A Case of Arson Discovered by a Surgeon.

A fire broke out in a cigar shop in Hulme, England, not long ago, and on the arrival of the fire brigade there were found to be three distinct fires in different parts of the shop and house. The two firemen who first entered were nearly suffocated by a dense white smoke, and applied to Mr. Heslop, Divisional Surgeon, Manchester police force, a day or two after, complaining of a rawness of the throat and chest, very different from anything they had experienced before. On account of what they told, Mr. Heslop burned some phosphorus in their presence, and they at once recognized the smell. Some phosphorus was then placed in some shavings, and it ignited spontaneously in about eight or ten minutes, and in sawdust in about twenty minutes.

Errors in Delicate Weighing.

M. Hennig de Wurtzbourg having noticed some incomprehensible differences in the weights of equivalent quantities, undertook some minute investigations, which showed that balances of precision are often influenced by the electric state of the glass cage which surrounds them. This electricity influences the small auxiliary slides which are placed upon the beam of the balance in order to make it more sensitive. The error resulting from this influence may amount to 600 milligrammes when the cage is strongly charged, and two hours afterwards there may still be an error of ten milligrammes.

Mange in Horses.

Sir J. Don Wauchope, Bart, states that the late Mr. William Binnie, of Carfrae Mill, near Lauder, who horsed several of the stage coaches which traveled that road, had mange—very badly—among his horses. He

found spirit of tar, in the proportion of half a bottle to one bottle of water, a never-failing medicine. When the case was a very bad one, he sometimes (the day after) rubbed the animal over with whale oil and sulphur. The animal should occasionally be washed with black soap and warm water. A little alterative medicine may also be given. The application of the spirit of tar in the above proportions should not be discontinued until the mange quite disappears. The spirit of tar mixtures ought to be applied with a brush.

Expert Testimony.

Judge C. C. Fuller, of Mecosta county, in the case of "State of Michigan *vs.* Vanimmans," decided, when a physician refused to testify on the ground that the evidence would be expert testimony: "After many years' study and observation, I decide that a physician's knowledge is his stock in trade, his capital, and we have no more right to take it without extra compensation than we have to take provisions from a grocery without pay to feed the jury. The court rules that the witness is not compelled to testify."

An Ingenious Diagnosis.

The *Med. Age* says that some physicians are very ingenious in devising causes for the ailments which their unerring power of diagnosis determines. One of these discovered the cause of the lead-poisoning from which he declared his patient to be suffering, to be the habit of sucking a lead pencil. The patient did not know that lead pencils do not contain lead; neither did the doctor—but that made no difference.

Sir Thomas Watson and Sir James Paget.

At the recent banquet of the British Medical Benevolent Fund, Dr. Broadbent, in proposing the health of the chairman, Sir James Paget, applied to him the words Sir James himself had used of Sir Thomas Watson: "His knowledge was so vast, his goodness so great, and his example so elevating, that we all wished he might spend part of his immortality on earth."

Cremation in Australia.

The legislature of New South Wales has passed an act which legalizes cremation in that colony. Crematoria are to be established. The plans must pass the Board of Health, and every applicant for a license must satisfy the Governor that he is the owner in fee simple, and has general consent to allow of cremation upon the land.

International Medical Congress.

Dr. Banks, Regius Professor of Physic in the University of Dublin, and Dr. John William Moore have been made Vice-Presidents of the Congress.

Items.

—Don't neglect to give the baby a drink of water once or twice a day. The nursing baby cries oftener from thirst than hunger.

—The New York Academy of Medicine has received a legacy of $25,000 from the late Mr. Woerishofer. Prof. A. Jacobi will formally present the gift.

—Sir William Stokes (Dublin) and Mr, Ernest Hart (London) have accepted the offices of Vice-Presidents of the International Medical Congress, Washington.

—In the *Boston Med. and Surg. Jour.*, October 14, Dr. Arthur H. Nichols reports a case of fatal poisoning by chloride of zinc applied to an epithelioma of the lip.

—Swift once said that the reason a certain university was a learned institution was that most persons took a little learning there and few brought any away with them, and so the learning accumulated.

—A school board recently asked the following question of a little girl: "What is the plural of man?" "Men." "Very well; and what is the plural of child?" "Twins," immediately replied the little girl.

—"Mamma," said a little girl, "I think I will soon begin to raise a mustache." "Impossible," replied the mother, "girls cannot raise a mustache." "Yes, they can, for I saw Annie raise Cousin Charlie's mustache when she kissed him, and that's how I mean."

—"Is the doctor in?" inquired a patient of the housemaid of a physician. "No, he is not," was the reply. "When would I be most likely to find him alone?" "Well, his office hours are from two to three in the afternoon. Call then, and you will be pretty sure to find him alone."

—Dr. T. E. Wright has carefully investigated the question, "When is a man drunk?" and decides as follows: "When consciousness becomes modified, in any degree whatever, through the influence of alcohol, and when, or as long as no exercise of independent nervous force is adequate to restore it to a normal state, the man so affected is drunk."

Pallas Syringe."

[From the *London Medical Record.*]
"It is a useful Instrument, and will be a formidable rival to the ordinary vaginal douche,"

SOLUBLE
PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

R[illegible] BERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

105-15556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superintendent and his assistant Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful Home.

DRESSINGS AFTER AMPUTATIONS AND OTHER OPERATIONS; PRACTICAL ANTISEPSIS ILLUSTRATED BY CASES.*

BY THOMAS G. MORTON, M. D.,

One of the Attending Surgeons to the Pennsylvania Hospital, etc.

Gentlemen: The case of amputation of the right leg in which the operation was performed three weeks ago in your presence, has had the original dressing disturbed but twice since you saw him, and simply for the purpose of removing the drainage-tube. His temperature has been absolutely normal since the operation. You remember that he likewise had a crush of the left tarsus, a fracture of the clavicle and of several ribs of the right side, which he suffered at the same time he received the graver injury for which the amputation was performed. He is doing well in every respect. In future I shall rarely use the drainage-tube, but substitute cat-gut drains, for I find that the tubes are really not necessary, and they require the dressing to be opened earlier than desirable.

TEALE AMPUTATION OF THE LEG.

The first case I will now show you is a man upon whom I performed a Teale amputation of the leg in your presence three weeks ago to-day. The dressings then applied before you have not been removed since then. The object of treatment by the antiseptic method is to avoid suppuration, and to get union at once. When bone has been divided, it is particularly desirable to obtain immediate union, on account of the liability to necrosis. This I am satisfied has occurred in the case before us, but we shall see. Upon removing the dressings, you observe that they are perfectly dry; they are discolored in the immediate vicinity of the wound by some leakage of bloody serum, which occurred a short time after the operation, but which has been so trifling in quantity that the dressings are hardly soiled; no more beautiful illustration of the results you may expect in using strict antisepsis can possibly be found than in the stump before you. You remember that I told you that the rule in making the long flap in a Teale amputation was to take the circumference of the limb at the point where you decide to divide the bone; the long flap then is to be made one-half the circumference of the limb. For instance, if this should be ten inches, then the length of the long flap ought to be five inches, and its breadth the same; the short flap is to be made one-fourth the length of the long one. All the tissues are dissected free from bone, which is then divided at the point previously determined upon, and the vessels having been secured with cat-gut cut close, the flaps are brought together with the interrupted cat-gut suture. The end of the bone is thus well covered, and the cicatrix is at the side, where it will be free from pressure. This makes the most satisfactory stump for the adjustment of an artificial limb. The wound was now entirely united, and the patient is ready for his discharge. Upon the surface of the dressings, lying in contact with the stump, are the re-

* Delivered October 23, 1886.

mains of the cat-gut ligatures and the cat-gut drainage; those portions of the cat-gut which were internal have been absorbed, those outside or external are those which I show you, and they are shriveled and quite dry. All the cat-gut included within the flaps, sutures, and drainage has been completely absorbed.

Now, here has been division of bone, of nerves, of blood-vessels, of muscles, and the other structures of the leg, followed by union without a drop of pus; in other words, union by first intention. When you reflect upon this result of primary union—glueing the parts together just as a piece of broken furniture can be glued together—is it not indeed remarkable? In 1804 there was a case of primary union after amputation of an index finger in this hospital, and it was so unusual that the fact was recorded as a "curious circumstance attending the healing of a wound." The report states that "no inflammation came on after the operation, and nothing like pus was observed during the healing of the wound; granulations did not arise, neither was a cicatrix formed, but the stump was healed by an extension of the old skin." Here was antiseptic healing without antiseptics. What was then a marked exception has now become the rule.

The character of the dressings which we apply after amputation in order to secure union without suppuration will be demonstrated before you as has already been done at my former clinics, and will now be done again in connection with another case upon which I intend to perform a Teale, or rectangular, flap amputation upon the right leg, on account of deformity following ulceration of the heel.

PARTIAL AMPUTATION OF THE HAND.

But first let me ask your attention to the results of some of our operations. The patient before you, a young man, on account of a serious injury, has been subjected to a partial amputation of the hand. The operation was done more than three weeks ago, and the wound has not been dressed since. He has not had a single unfavorable symptom since the operation. He is well and would have been discharged yesterday, but was kept here until to-day in order that you might see the dressings taken off.

The operation was performed by my son, Dr. Morton, Jr., with the usual antiseptic precautions. The hand was badly crushed, so that a partial amputation was required, leaving only the thumb and part of the little finger. On removing this, the first dressing, you see the wound entirely healed; there is no odor, and there has been no suppuration.

COMPOUND, COMMINUTED, DEPRESSED FRACTURE OF THE SKULL.

Two weeks ago last Thursday, this man, aged twenty-two, was brought in suffering with a compound, comminuted, depressed fracture of the parietal bone. I trephined the skull so as to allow the elevation of the depressed portion. The wound was cleansed and dressed in the same manner as the preceding cases. The dressings have not been removed since they were first applied. His temperature did not go above 100° after the operation, and on the second day was normal, and has remained so. In forty-eight hours after the dressings were applied, he was allowed to get out of bed; he was without any symptoms whatever after this severe operation, which formerly involved a stay of weeks, and sometimes months, in the house. It is now sixteen days after the injury, and the primary dressing is now taken off. Here is the gauze compress slightly discolored with dry blood. The sutures, that is to say, the portion of them lying external to the wound, are left free upon the dressing, and I pick them off and ask you to examine them. There is no pus upon them, and there has been none. The wound has entirely healed. The line of incision, which was three inches long, has united throughout its entire extent by primary union, and the few catgut threads introduced for drainage have disappeared. There is an especial advantage in these head injuries from this method of treatment. Fungus cerebri, as you know, is due to inflammation of the brain-tissues, which push out granulations through the softened meningeal structures; cerebral matter may also protude, owing to pus accumulation in the hemisphere below. The way to escape hernia cerebri is to prevent suppuration; it never takes place where there has been primary union. Having the results of antiseptic methods, as illustrated in this case, in mind, would I be justified, think you, in treating another case of this kind in any other manner, and have suppuration with the risk of fungus cerebri, when I have the means of absolutely preventing it?

HAY AMPUTATION OF THE FOOT.

Here is another amputation. This boy was admitted on the 10th inst., with a crush of the forepart of the foot requiring a Hay amputation. The operation was done by my son late at night. I was present and assisted

the dressing which was applied just as you have already seen, and it has not been disturbed since. You are all aware of the seriousness of a tarsal amputation where the joint is involved, and where the muscles, nerves, and blood-vessels are crushed or torn the danger is greater. The result in this case you see before you. This is the original dressing, which has not been removed until now. There is absolutely perfect union, and I have never seen a handsomer stump than in this case.

Gentlemen, these are not picked cases that I have brought before you this morning; they are the ordinary cases from the wards. What an advantage this method of surgical dressing should be to the physician who practices in the country, where, owing to the distance daily visits to patients may be an impossibility. What a relief to the surgeon's mind when he knows that the primary dressing need not be disturbed in many cases for weeks, or indeed until the patient is well. Take an ordinary case of surgical injury requiring operation, coming into the hospital in past times. There was usually more or less surgical fever and suppuration after grave and indeed even ordinary operations. During the period of the fever the patient is unable to take food in sufficient quantity, and his strength and powers of repair are correspondingly impaired. What an advantage to the surgeon then it must be for him to be able to prevent suppurative fever after operations, for by this means the patient has no interruption to his nutrition, and repair must be greatly facilitated.

RUPTURE OF LONG TENDON OF BICEPS MUSCLE; SUTURING OF TENDON; RESTORATION OF FUNCTION.

I will now show you the result of an operation which I was able to perform successfully with the aid of these dressings, and which without them I would not have dared to attempt. This man came in the other day with a rupture of the long tendon of the biceps muscle. He is a laborer, and was at work in a pit, standing at the bottom and throwing shovelfuls of dirt out of the top, which was above his head; suddenly he experienced a pain in his right shoulder, and he was unable to continue at his work. I found upon examination of his arm that the long tendon of the biceps had been ruptured by muscular effort. The muscle was contracted and in a state of spasm, the tendon was torn loose from its attachment to the scapula. With the results of the other cases in mind, I determined to perform a novel operation; I cut down upon the biceps muscle, and found its tendon coiled up upon it like a worm. I cut off the frayed end of the tendon and replacing it in a deep groove which I cut in the deltoid (which I had exposed to the acromion), I stitched it fast in the tissues of this muscle. The usual dressings were applied, and the arm kept in a sling. That was sixteen days ago. The dressings have not been disturbed since; they will now be removed. You see here the line of the incision, which has perfectly united. Some remnants cat-gut of sutures are lying upon the dressings, which are perfectly dry. Although the wound has healed, we will not allow the man to use his arm yet; he should not go to work again for another fortnight, but there is no need of keeping him in the hospital all that time. He can report at the out-patient department, and carry his arm in a sling until the tendon has united firmly in its new location.

GUN-SHOT WOUND OF POPLITEAL SPACE.

Two cases came in on last Thursday afternoon which I regard as crucial tests of antisepsis. They will now be brought before you.

The first man was shot while up in the mining regions, and received a wound in the popliteal space with a pistol bullet, which remained deep in the wound. Upon examination I came to the conclusion that the ball must have injured important deep structures, since the wound was directly in line with the large blood-vessels and nerves, and that possibly it had entered the joint. Sensation in the parts below was preserved, but there was no pulsation in the anterior tibial artery or its branches in the foot.

With antiseptic precautions, I opened the popliteal region and found the ball lying some distance beyond the artery, it having also injured and opened the knee-joint. The bullet, which was from a Smith & Wesson revolver of small size, had completely divided the popliteal artery, and had wounded but not opened the accompanying veins. The divided ends of the torn artery were then carefully isolated, the proximal end was filled with soft clot, the other end was patulous,and both ends were securely tied in order to prevent secondary hemorrhage. I used cat-gut ligatures, which were cut short, and the wound was then closed in the usual way. The patient has had only slight rise in temperature since the operation, and has been perfectly comfortable. An injury of this kind has been always considered a grave one, and one in which under other forms of

treatment would call for amputation. I need not stop to point out the great difference between the results of treatment by former methods and those which we have obtained here by strict antisepsis.

LACERATION OF KNEE-OPENING OF THE JOINT; RECOVERY WITHOUT ANKYLOSIS.

The second case is one in which the knee-joint was entirely exposed by a fall that ruptured old inflammatory adhesions, which had been thrown out in nature's attempt to unite by new tissue a ligament of the patella ruptured more than a year ago. The skin and deep tissues were so torn as to expose the condyles of the femur and the articular surface of the tibia, the lateral and crucial ligaments were torn, and the wound of the soft parts around the joint was so extensive that the leg was really only held by a posterior flap, in which, however, the vessels and nerves were preserved intact. I made lateral vertical incisions four inches in length, just as if I were going to perform an amputation, and so was enabled to clean out the knee-joint and adjacent wound with a douche of one to one-thousandth ($\frac{1}{1000}$) solution of corrosive sublimate. All clots were carefully removed and the wound surfaces carefully curetted. I then brought the parts together with about twenty catgut stitches, and dressed the wound antiseptically. His temperature this morning, forty hours after the operation, is only $100\frac{1}{5}°$, and his general condition is good. When you consider the character of the case: that he was in a bad condition, that he is a drinking man, and was under the influence of liquor when he received the injury, I think that you will agree with me that the result thus far has been remarkable. The object of the treatment was to seal up the joint and to prevent the occurrence of irritation and suppuration. [The patient recovered without a bad symptom, with a movable joint.]

HÆMATOCELE OF THE THIGH.

The next case is one of contusion of the upper part of the thigh, with a large hæmatocele, just above the knee, of one week's duration. I will now have the part thoroughly shaved and washed clean with bichloride solution, and then cut open this sac from one end to the other. My incision is five inches in length; I turn out the clot and wash the cavity with a one to one-thousand solution of corrosive sublimate. With a sharp spoon I am now scraping the walls of the cavity so as to remove all disorganized shreds of tissue and blood-clots; this having been done I unite the edges of my incision with interrupted catgut sutures, and apply a compress of gauze wet with the same solution. Iodoform is thickly dusted over the wound, and absorbent cotton, previously washed with the mercuric solution, is next applied and retained in place with a bandage wet in the same solution. A few strands of catgut ligatures are placed in one angle of the wound so as to admit of drainage, and a straight splint is placed on the back of the limb to insure rest.

TEALE AMPUTATION FOR CICATRICIAL DEFORMITY OF THE FOOT.

The next case is a man from the mining regions, upon whom I will perform a Teale amputation. About a year ago he was injured by a falling mass of coal, which crushed his right heel. This accident was followed by prolonged suppuration and ulceration. As a result, there is contraction of the plantar fascia and of the gastrocnemius muscle to such an extent that he has an acquired talipes equinus; the foo is permanently extended and averted so that he walks upon the base of the big toe. Anchylosis of the tarsus and ankle-joint has taken place, the sole of the foot is only covered by a thin skin or scar-tissue, which is adherent to the bone beneath.

The only remedy for this state of affairs is amputation and an artificial limb.

It is always best before making a Teale operation to carefully measure the size of the flaps and mark their outlines with iodine or the point of the knife, you should never trust simply to your eye.

Proceeding now to the operation, the limb is first washed with soap and water and carefully shaved. It is next bathed with the 1 to 1000 solution of corrosive sublimate in water; and towels wet with the same are placed around the limb above and below the field of operation. The hands of the surgeon and assistants are also disinfected, likewise the Esmarch bandage before it is applied. The knives and other instruments for the operation have been boiled in water and are kept in a tray under a weak solution of carbolic acid, because the corrosive chloride would act upon the steel and dull them.*

The limb at the point of amputation measures ten inches exactly. The long flap, then,

* At the suggestion of Dr. Morton a collection of all the dressings and materials for making the different solutions for applying to wounds to secure antisepsis have been put into a box of convenient size by Mr. Geo. I. McKelway, 1410 Chestnut street, to whom inquiries relative thereto should be addressed.

will be five inches in length and breadth. I will take it from the outside or external aspect of the limb, because there is more healthy tissue here. The short flap I will now mark 1¼ inches long and five in breadth. All of the soft parts help to make up the flaps, which are now separated from the bones, and the tibula and fibula divided; the wound is washed with weaker solution of bichloride, and the vessels secured with catgut ligatures, which are cut short. Some strands of catgut, instead of rubber tubes, are placed in the lower angle of he wound and the flaps are brought together with catgut sutures.

The same dressing is applied as in our other cases. A line of silk protective is laid over the sutures, iodoform is freely dusted over the surface, gauze, and absorbent cotton, both having been treated with 1 to 1000th corrosive sublimate solution, are used to cover the stump, and kept in place with a bichloride bandage. Unless something unusual occurs, indicated by a rise in temperature (which shall be carefully recorded morning and evening each day), this dressing shall not be disturbed for three weeks. I will then bring him before you again and show you the result.

[One week after the operation, the patient is doing well—has had no fever, and has been out of bed for three days.—Rep.]

DILATATION OF THE CERVICAL CANAL, FOR STENOSIS OF THE INTERNAL OS, UNDER COCAINE.*

BY THOMAS A. ASHBY, M. D.,

Of Baltimore, Md.

It may be stated, without fear of contradiction, that the limits to the successful application of cocaine as a local anæsthetic have not been reached. The startling results following the introduction of this agent have been phenomenal and unprecedented in the history of medical discoveries. Scarcely had Dr. Koller made his observations before the event was spread over the entire globe, and surgeons in every country have vied with each other in successful experimentation with the newly-discovered properties of the agent. Following close upon the local use of cocaine to mucous surfaces, it was demonstrated by Dr. Corning, of New York, that the injections of the solutions of the drug into subcutaneous tissues, associated with circumscribed constriction of the surrounding parts, induced successful anæsthesia in the area into which the drug was injected. This discovery opened up a new field for local anæsthesia; a field which has been most diligently cultivated, with results of the most astonishing character. Amputations of limbs, removal of circumscribed growths, laparotomy, circumcision, and closure of hare-lip, are among the operations painlessly performed after the method inaugurated by Dr. Corning.

There is no longer a shadow of doubt as to the value of cocaine as a local anæsthetic, and its employment in surgical work is now only limited to the choice and care of the operator. All mucous surfaces are readily brought under its anæsthetic influences when solutions of sufficient strength are properly and carefully applied to the mucous membrane. The stronger the percentage of the solution, and the greater the length of time employed in its application, the deeper its penetration, and the more profound its benumbing influence.

My experience with cocaine convinces me that it may be employed with the greatest advantage in surgical gynecology, and that many operations upon the vagina and uterus, hitherto requiring general anæsthesia, may be successfully and painlessly performed when solutions of cocaine of sufficient strength are carefully applied to the tissues. I have employed cocaine in gynecological work in a number of conditions, with almost uniform satisfaction. A recent experience with this drug has induced me to relate the following case, which I think explains very satisfactorily its benumbing influence upon the cervix uteri.

Mrs. H., aged 23, married 18 months, has suffered from her first menstruation with violent dysmenorrhœa. The menstrual flow has invariably been announced with violent cramps, pains, and disturbances of digestion. During three or four days of menstruation the recumbent posture has been required, and a total inability to engage in domestic duties has been almost constant.

Though married 18 months, Mrs. H. has never conceived. Physical examination revealed a small uterus, occupying a low position in the pelvis. The uterus was very acutely retroflexed. The cervical canal was bent and so small as scarcely to admit the smallest probe. There was evident stenosis at the internal os. The diagnosis of obstructive dysmenorrhœa was established, and the

*Read before the Gynecological and Obstetrical Society of Baltimore.

dilatation of the canal was proposed for its relief.

The patient was averse to taking chloroform or ether, and expressed a willingness to endure the operation of divulsion with the use of cocaine. After a few days of preliminary treatment, consisting chiefly in the use of hot-water injections and attention to the stomach and bowels, the operation was undertaken. One-fourth grain of morphia was administered fifteen minutes prior to placing the patient on the table, and at the same time a cone containing one grain of cocaine, with five grains of boracic acid, two drops of oil of wintergreen, and cocoa-butter, q. s., was introduced into the vagina. The operation was then begun. The cone had melted promptly and was removed in a liquid state. The vagina was sponged out with warm water rendered antiseptic with bichloride of mercury (1 to 4000). A small sound was passed into the uterus and the fundus lifted up. The sound withdrawn, applications of cocaine were made at intervals of every three or four minutes to the cervical canal and to the vaginal cervix. The parts were benumbed as thoroughly as possible. The small bivalve dilator was next passed, and the canal stretched so that it would admit of the introduction of the larger blades of Ellinger's dilator. Before divulsing with Ellinger's instrument cocaine was again applied. In fact, the solution was used repeatedly during the operation. When I had succeeded in stretching the blades of the dilator to nearly their full extent, the instrument broke under the strain of the pressure with a sudden snap, which startled my patient. Apart from this she experienced no pain, and expressed herself as ignorant of what was going on. After removing the blades of the dilator I passed a No. 14 sound into the uterine cavity. Whilst the divulsion was not as complete as I desired to make it, in consequence of the breakage of the dilator, its good results were unquestionably shown. The patient was kept in bed one week. Menstruation came on on the fourth day after the operation, without pain and without nausea. The first sign manifest to the patient was the appearance of the blood on her linen. The result was surprising to her, as such freedom from distress was an unknown quantity in her history. Mrs. H. is now wearing a retro-uterine pessary, and is at present in comfortable health. As she has not passed through her second menstruation since the operation, I am unable to state what influence it will have upon her future health. I relate the case to show the fact that divulsion can be performed with cocaine without pain. I claim no originality for this use of the drug, but simply offer this testimony to induce my colleagues in gynæcological work to give the drug a trial, if they have not previously employed it for this purpose.

The strength of the cocaine solution used was four per cent.

CHARMS AND SUPERSTITIONS IN THE TREATMENT OF DISEASES.

BY WM. F. MITCHELL, M. D.,
Of Addison, Pa.

It seems singular in the latter part of the nineteenth century that in almost every locality relics of superstition and barbarism remain. I presume there is no country settlement where you can find more cultivation and refinement, where more newspapers and books are read, where churches and schoolhouses are more plentiful, than this, and yet there is hardly a family that does not cherish some superstition that has been handed down from generation to generation. Their name is legion. Among the remedies for hemorrhage from the nose or a wound is the repetition of certain words from the Bible, which, however, must be repeated by some one gifted in a certain way; as, for instance, the power must be originally possessed by the seventh son of a seventh son, and by him delegated to a woman (if a seventh daughter so much the better), and by her to a man, and so on alternating, but under no circumstances can a man impart the power to a man, or a woman to a woman. For uterine hemorrhage I have seen red and blue yarn strings tied around the fingers and toes, and even the knees and thighs; this too must be done by one having certain power. I remember one man whom I have followed frequently after his incantations failed.

Then, if a child is puny and of low vitality, a hole is bored in a tree the exact height of the child, a plug driven in, along with some hairs of the child's head, the belief being that as the tree continues to grow so will the child. A tea made from the fresh excrement of a sheep is considered a sovereign remedy for measles, and I have actually known people who were ordinarily intelligent to drink it by the pint or more. The juice of the excrement of a stallion, voided before sun-up in the morning, has been given for certain intestinal troubles, colic, etc., including epilepsy. In justice to my patrons, I will say that the knowledge of this last remedy was obtained in another community

where I formerly practiced. The excrement of the cow has been used frequently as a poultice in abscesses and also in rheumatism. Toothache is treated by a branch from a sweet-apple tree, cut in a certain phase of the moon, sharpened at both ends; the branch or twig may be an inch or two long, prepared and used by a certain person with occult power. Then the tooth is picked until it bleeds; if an upper one, with the smaller end, if a lower one, with the large end. Freckles are supposed to be removed by washing in the water contained in a hollow stump three successive mornings, commencing on May 1 before sun-up.

The cures for warts are many, among which may be mentioned tying them with a string, that is, tying a knot over each wart, and burying the string at the northeast corner of the house, under the eaves; rubbing the wart with a slice of potato, and feeding the potato to the hogs: blowing them away with the breath, or by repeating words. All these cures, however, must be performed by a certain person, one with some mysterious power gotten in some way. If a boy is fishing and gets dirt in his eye, he will hunt a craw-fish, and, carefully enucleating one of its eyes, insert it in his own. I knew a very intelligent man, who had ophthalmia in its most simple form, but which proved a little intractable, to allow himself to be treated by a man who absolutely knew nothing about medicine, and whose treatment consisted of some secret and mysterious incantations, known only to the patient and himself. If a new-born child is handed to its father to be kissed before it has taken anything in its mouth, it is believed it will never get a sore mouth. In dressing an infant the first time, if the clothes are put on over the feet, it will always be even-tempered, and will not cry.

These are only a few of the many superstitious cures. To give anything like a comprehensive account of all would make this communication too long. Mention of a few other superstitions in regard to every-day life may not be out of place.

Only the other day two ladies were walking along the street, when one of them inadvertently passed on the other side of a tree, beside which they were walking, the other immediately came back and went on the same side her companion did, in order, as she said, that their friendship might not be divided. For the same reason I noticed a mother whose son was walking with two other young men, and who went on the opposite side of a tree, make her son turn back and walk on the same side.

To carry a shovel, hoe, or any iron agricultural implement through a house, is supposed to be a sure sign of the death of some member of the family. They can, however, be carried *in* the house to any extent, if they are brought out the same door they were taken in. A garment must never be cut out on Friday on any account, nor on Saturday, unless it is sure to be finished on the same day, otherwise death will follow. If the thread kinks and curls up when a garment is made, the wearer will not live to wear it out. If a person starts to go anywhere, forgets something and comes back, he will have bad luck. The new moon must be seen over the right shoulder, if health and strength are valued.

A great many other superstitions prevail in regard to planting seeds, butting timber, making fence, roofing houses, killing hogs, etc., not to mention the belief still extant in some localities in regard to witches, ghosts, and supernatural sights and sounds.

PAPILLOMA OF THE LARYNX.

BY ALEXANDER W. MAC COY, M. D.,
Of Philadelphia.

Ernest S———, aged eight, a native of Chester county, and a patient of Drs. Isaac Massey, of West Chester, and H. Darlington, of Concordville, was referred to me in July, 1884, for treatment for papilloma of the larynx. The child's parents give the following history: One year and a half before coming under my observation they had noticed that the lad was suffering from a mild catarrhal laryngitis, accompanied by a slight cough. A few months later, they noticed the lad's voice changing—becoming thin, shrill, and often breaking. This condition continued for six months, his voice coming and going. Nearly one year afterwards, his voice had become reduced to a mere whisper, and only with great effort could he raise his voice to a *hoarse* whisper.

About this time the lad complained of oppression, and some pain in the chest. A few months before, his parents had first observed difficult breathing, but not until three weeks before I saw him had the attacks of dyspnœa become frequent or alarming. Severe attacks of difficult breathing occurred at night, and often lasted for hours, and suffocation appeared inevitable.

At his first visit to me his breathing was quite loud, stridulous, both on inspiration and expiration, more marked on *inspiration*. His face was pale and anxious; pulse soft,

irregular, and rapid; inspiration and expiration laborious, giving the impression that suffocation might occur at any moment. The lad had lost flesh rapidly during the previous three months.

Laryngoscopic examination showed the lumen of the glottis greatly encroached upon by a grayish, pinkish mass, irregular in outline, completely obscuring the left vocal band. The mass appeared thick, and piled up on the vocal band, overlapping and overhanging the free edge, and descending underneath the left vocal band. The right vocal band was *less* involved; a growth of considerable size appeared to spring from underneath its middle. There was, in addition, a *sub-glottic growth*, which on deep expiration was seen through the rima-glottidis filling up the entire chink, except a small space at the posterior portion. This growth appeared to spring from the anterior angle of the thyroid cartilages, just beneath the anterior commissure of the vocal bands. This mass was very freely movable on respiration—*inspiration* drawing it down into the trachea almost out of sight, while *expiration* forced it *up* into the chink. This condition of affairs produced a most novel effect—a constant bobbing up and down during respiration—and at the same time constituted a state of imminent danger to life. It was under such circumstances, demanding instant action, that I was called upon to decide upon the proper treatment. The child had already been examined by another laryngologist of this city, who refused to do anything prior to a tracheotomy. The parents were averse to subjecting him to what they deemed an additional risk, and were anxious to have an attempt made to remove the growth before tracheotomy should be resorted to. Accordingly, the growth *was* removed by the intralaryngeal method without tracheotomy or previous training of the larynx, and necessarily without cocaine, as the operations were performed prior to its use. The several growths were removed at various sittings by Mackenzie's right-angled forceps (cutting and blunt) until the larynx and trachea were entirely free from the papilloma. The tendency to recurrence was checked by the application of fused chromic acid. At the present writing the lad's voice is fully restored in volume and character, and the anatomical features of the interior of the larynx are intact.

1417 *Walnut St.*

STRANGULATED FEMORAL HERNIA—OPERATION—RECOVERY.

BY A. D. BUNDY, M. D.,

Of St. Ansgar, Iowa.

In response to an editorial for a more frequent report of cases by practitioners, I submit the following:

Mrs. T———, a Scandinavian by birth, a small and frail woman, who had borne five children, and whose health was impaired from hard work and uterine disease, and whose age was about thirty, had been for two years a subject of femoral hernia. She had in vain tried to wear a truss, but could find none that could be borne but a few hours at a time; consequently her hernia came down often, but she had always succeeded in reducing it until Sunday, September 26; then all means at her command failing, I was sent for, but did not reach her until Monday morning, the 27th. She had been in much pain all night, and vomited several times. Recognizing the gravity of the case, I sent for my friend, Dr. Cobb, of Mona. On his arrival, ether was administered, and we both tried taxis in every position conceivable that would favor reduction; but our efforts were of no avail. She was now placed on an ordinary kitchen table and in a good light, when with antiseptic precautions I proceeded, with Dr. Cobb's aid, to operate. The skin was incised in the usual way, and with my forefinger I swept around the hernial sac and cleared it of its facial coverings, and soon found the constriction. The sickle-shaped process could be easily made out, and my forefinger point insinuated under it, but I could not rupture it; but with the bistoury carefully guarded, it was cut sufficiently so that the hernia could be returned. Not a teaspoonful of blood was lost in the operation.

The wound was now united with silk sutures and a dressing of subnit. bismuth dusted on, and covered with sublimated gauze. I did not disturb the dressing for three days; at that time the gauze was slightly stained. The wound was cleansed by wiping with borated cotton, and I now covered the wound with iodoform, probably dusting on one-half a drachm covered with sublimate gauze, and over that a compress of borated cotton. In twelve hours my patient showed unmistakable signs of iodoform poisoning. The symptoms were pain about the heart and faintness, with feeling of fullness in the head; and although I instantly removed the dressing and substituted bismuth, it was two days before she entirely recovered

from its effects—this being the first time I ever had seen any ill effects from iodoform. The small quantity used in this case suggests to my mind that a peculiar idiosyncrasy exists in those cases in which the drug is peculiarly noxious. This being my first case of herniotomy, and not making any special pretensions to do surgery, causes me to thank my stars at the favorable result of the case, as my patient is now well and doing her work.

Medical Societies.

GYNÆCOLOGICAL AND OBSTETRICAL SOCIETY OF BALTIMORE

Regular meeting, held October 12, 1886. Dr. L. E. Neale read a paper on

Removal of the Uterine Appendages for Fibroid of the Uterus—Recovery from Operation.

Martha Bayton, colored, æt. 27 years, Va. An intelligent domestic, never pregnant or married. General health good, and early history unimportant.

She first observed an abdominal enlargement during the fall of 1884, *i. e.*, about two years from date, and the increase of this enlargement was accompanied by a gradnal diminution of the menstrual flow, which, however, remained perfectly natural in other respects. The abdominal enlargement, it seems, was ascitic, for she had been tapped by another physician in October, 1885, when a large quantity of straw-colored fluid was removed, after which a tumor in the right iliac region was quite perceptible.

The fluid reaccumulated, distended the abdomen to 41 inches in its greatest circumference, and forced the posterior vaginal wall outside of the vulva, whence it protruded as a soft tumor about the size of a small cocoanut. There was no procidentia uteri, and the somewhat tortuous uterine canal measured three inches. I found the patient in this condition, with an abdominal tumor extending to the level of the umbilicus on the right side. The tumor was apparently movable, seemed to be free of all adhesions, floating in the ascitic fluid and attached to the pelvic organs by a supposed pedicle.

As regards the nature of the tumor no positive diagnosis was made before the operation. Although the tumor seemed so freely movable in the ascitic fluid, the failure of the uterus to descend with the posterior vaginal wall, in the absence of other recognizable cause to sustain it in its high position (for the tumor did not fill up or press upon the pelvic brim) might have led to the diagnosis of adhesions, which, as already mentioned, were not suspected in this case.

The patient was in fair health, which was, however, beginning markedly to run down, and, although greatly inconvenienced by the abdominal distention, she was able to continue her household work up to date of admission into the University of Maryland Hospital, September 15, 1886.

The operating room was fumigated with chlorine gas generated by igniting a mixture of equal parts of ether and chloroform; it was then thoroughly scoured, cleaned and ventilated.

The spray was not used at any time, and the water, previously boiled, was carbolized too little to destroy germs.

The usual preparation of the patient was observed.

Operation, September 18, 1886, 11 a. m.

Incision in the median line finally enlarged to three inches, and about three gallons of ascitic fluid removed. The tumor was found to be a non-pediculated, sub-peritoneal uterine fibroid, growing from the right cornu uteri and strongly adherent to the right anterior abdominal wall. Salpingitis and periovaritis existed on both sides, the appendages being closely and firmly adherent to the uterus.

All things considered, removal of the uterine appendages was judged to be the most favorable and practicable operation. This I found under the existing conditions a very difficult task; indeed, I do not hesitate to say, it might have proved too difficult save for the presence of my kind friend and teacher, Prof. Wm. T. Howard, who, both by wise counsel and practical help, assisted materially in the performance of the operation. For this I am happy to make public acknowledgment and to express my sincerest gratitude.

Silk ligatures were used, and applied close against the uterine wall; the abdominal cavity was washed out with warm water poured into it from a pitcher; the incision was closed with ten silk sutures and the usual simple dressings applied.

Duration of the operation nearly two hours. The patient rallied well, convalesced uninterruptedly. A menstrual-like flow occurred from the third to the seventh day after the operation. The sutures were removed on the sixth day. Patient discharged on twenty-first day, viz., October 9, 1886, with no return of the ascites; incision thoroughly united and shrunk to 2½ inches in

length; tumor sunk below umbilicus, making only a slight prominence through the abdominal wall; vagina retracted into normal position, and patient's general condition quite good.

I believe I am right in stating that in this case no positive diagnosis was made before the operation, although I must qualify this by saying that Prof. Howard did incline towards a solid tumor, and inasmuch as fibroids of the uterus are the most frequent abdominal tumor in the African race, he *suspected* a fibroid.

The ascites was gradually reducing the woman's general condition and rendering her unfit for work. No other cause for the ascites was discoverable save the presence of the tumor. A previous tapping had afforded a very brief relief, and she was anxious for an operation in order to obtain either temporary or permanent benefit. Hence, it was determined to withdraw the fluid through an exploratory incision, anyhow, and then remove the cause of the ascites if practicable. At the operation it was found that the removal of the tumor would have been very difficult and dangerous on account of its strong adhesions to the anterior abdominal wall, and as it was non-pediculated would have necessitated supra-vaginal hysterectomy. The mortality of this operation under general operators (excepting Keith and a very few others), when compared with the natural death rate from fibroids—particularly non-bleeding sub-serous fibroids—we know to be fearfully discouraging; indeed, I had almost said, render the operation unjustifiable. In my case peri-ovaritis and salpingitis existed on both sides, in all human probability unfitting the woman for generation; moreover, the fibroid was not very large; and for all these reasons, with the full concurrence of all present, Prof. Wm. T. Howard included, the least of the two serious operations was selected, and as it seems with a satisfactory result.

Although I propose in this little article merely to give a brief clinical report of my case, leaving the general subject of castration to be disposed of by older, more competent, and more experienced men, I cannot refrain from touching upon a few interesting points in connection with the operation, in the hope of eliciting instructive remarks from the members of the society.

I do not hesitate to say the most thorough, interesting article upon the subject I have been able to obtain, is that Olshauen, published in the *Handbuch der Frauenkranheiten*, vol. ii., ed. 1886. As this has not yet been translated into English, and hence is practically a closed book to some of us, I shall here take the liberty to quote a few brief passages with especial reference to castration when performed for uterine fibroids.

Speaking of this operation when weighed against myomotomy, which, as I understand it, includes supra-vaginal hysterectomy, he (*op. cit.* vol. ii., p. 709–10, etc.,) says: "I do not believe the time has yet arrived, when we can give a correct judgment with certainty upon this point. It should, nevertheless, be remembered that Hegar and Wiedow, from the most recent observations upon large fibroids, even when subserous in character, hold castration to be very successful, and hence they, together with Kn. Thornton, limit the indications for myomotomy to pediculated and cystic myomata."

The termination of this question, Olshausen thinks, must be governed by the given case and the operator, and that no absolute rule can be made. President Reamy, speaking upon this subject, in his address before the American Gynæcological Association, recently assembled in this city, said: "The operation of hysterectomy should not, as a rule, be performed in these cases. Spaying has met with more favor and success than any other surgical procedure."

Hays' Journal for October, 1886, states: "Though the value of castration may have been disputed by several authors on theoretic grounds, yet all objections to it fade away before the statistics compiled by Wiedow, which justify us in regarding castration as the operation to be preferred in uterine fibromata." (p. 604.)

With regard to the results of castration for fibroids, Goodell (Virchow and Hirsch, ib., 1878, ii., p. 568,) collected ninety-eight cases; in seventy-eight of these amenorrhœa occurred, in eight menstruation became more difficult, and in twelve it persisted.

Wiedow, in later statistics, reviews 76 cases, in which the menopause occurred at once or after slight bloody discharges in 61 cases. In only four cases was the effect upon the hemorrhages temporary or nil. In 63 cases the fibroids diminished. In 3 cases a primary diminution with a subsequent increment of the tumor was observed. An observation similar to this is recorded by Hofmeier.

The time required for a decided effect upon the hemorrhages or the tumor, we would naturally expect to be very uncertain and indefinite, when we remember that the operation when thoroughly performed and successful, merely prevents the periodic monthly

uterine congestions or establishes the menopause, but in nowise affects the uterus or the tumor. Hence, the desired result may occur at once, or not for years, and it is therefore possible, if not highly probable, that some results might readily be attributed to science which are really due to nature, the woman having attained her natural menopause. In some cases the decrease of the tumor is rapid and very marked; thus, Lawson Tait observed a five-pound fibroid entirely disappear in six months after the operation. In a case where castration was performed, intrapartum (for fibroids) Williams observed the uterus to diminish to a size less than its virgin condition, the uterine cavity measuring only two inches in seven months after the operation.

Olshausen says in one case he has also observed a marked and rapid involution of a large fibroid after castration. This patient was 39 years old, was in a profound state of anæmia, with general œdema, and entered the clinic in such an exhausted condition that it was only after a considerable time he dared to perform an operation. The uterus was of the size of a seven to eight months pregnancy. Three months after the operation the tumor had shrunk to one-half, and one year later to one-third its former size, and so it had remained after four and a half years, when he made his last observation. In this case menstruation never returned; the woman became the very picture of health, and performed the heaviest farm work. Amenorrhœa did not occur at once, but there was an almost continuous bloody discharge for 6 to 11 months after the operation; then the bleedings occurred irregularly, with intervals of half a year, until they finallly disappeared entirely, three years after castration. But the general condition so markedly improved during the first half year that a favorable result was then apparent. In another case, 37 years old, the menopause occurred at once and continued 2½ years afterwards, when last seen. It should be noticed that among those cases in which the menopause occurred at once there was one case, and the only one O. has observed, in which the ovary was removed only on one side, as it was impossible for him to find the other ovary. Of course, the probabilities are that it was functionally destroyed and hidden by disease, or indeed, may have been congenitally absent. Leopold in one case failed to extirpate any ovary, but merely ligated several blood-vessels, and yet no further uterine hemorrhage occurred.

According to Olshausen, amenorrhœa occurs in three-fourths of all cases of castration, and remains permanent. A slight uterine hemorrhage of several days' duration, here, as after ovariotomy, may occur several days after the operation without signifying true menstruation. This may continue for hours, or days, but is rarely profuse. Schrœder holds that a small bit of ovarian tissue left after supposed removal of the ovary may prove sufficient for a continuance of function. And, again, Dr. Spencer Wells (*American Journal of Medical Sciences*, October, 1886,) tells us: "Wiegel counted, out of six hundred women examined, no less than twenty-three with more than the ordinary two ovaries." "Instances of regular menstruation, and even of pregnancy after double ovariotomy, have been met with sufficiently often to show how easy it is for the expectations of a surgeon to be thwarted by a condition which he can neither foretell nor determine exactly at the time for his operation."

Such cases, however, are, of course, the exceptions. The largest and most recent statistics of castration for fibroids, according to Olshausen, is furnished by Wiedow, who gives 149 cases with fifteen deaths, or a mortality of ten per cent. Eleven of these deaths were due to septic peritonitis. I have never seen the statistics of Mr. Lawson Tait, and other leading operators in this field, for castration when performed for uterine fibroids, but suspect the mortality must fall below ten per cent.

Although it does not pertain strictly to the case herein reported, I am sure it would be interesting to hear an expression of opinion from those who have performed castration for psychical or other disorders not connected with fibroid tumors of the uterus, and when no anatomical evidences of disease are recognizable in the ovaries or appendages.

In this connection, Olshausen reports an exceedingly interesting case of a woman, twenty-six years old, who for ten years had suffered severely from a number of disorders, and among others from paralysis of the inferior extremities. Every evening at a certain regular hour convulsive attacks of the most violent intensity occurred, lasting, with short intervals, for one-half hour, during which time she was unconscious. Each attack was announced by pain in the region of the left ovary, and these pains continued during the entire night of the attack. Whenever the ovary was touched during an examination, with or without narcosis, pain was experienced, which continued for several hours. Besides this, there were slight attacks

of epilepsia brevis, or *petit-mal*, occurring often during the course of the day, at which times the eyes were closed, the head fell upon one side, and after one-quarter to one-half of a minute the patient awoke to consciousness.

All treatment proved *nil*, and often these violent convulsive attacks had continued daily for ten entire months. On the 26th of September, 1881, castration was performed without difficulty. At the operation not only were the ovaries found to be perfectly normal, but not even had any inflammatory process existed in the surrounding tissue. However, on the very evening of the operation the convulsions failed to occur, and as yet, in four years, have never returned, as also has not menstruation. The attacks of *petit-mal* continued during the first months after the operation, somewhat more frequent and severe than before, but after half a year they appeared less frequently, and finally disappeared altogether. The general condition of the patient improved from the very day of the operation. Similar cases are reported by Mäurer, Heilbrun, etc., and many others have appeared in our own English literature. In Olshausen's own words, this case illustrates very plainly that there are cases of severe cerebral and spinal symptoms, where, notwithstanding the absence of all recognizable abnormalities (in the ovaries), castration may be performed with great advantage.

Sir Spencer Wells, in the October 1886 number of the *American Journal of the Medical Sciences*, "repeats a warning made in 1882, that although he accepts the principle, he sees that the operation has a very limited application, and is so open to abuse that its introduction in mental and neurotic cases is only to be thought of after long trials of other tentative measures and the deliberate sanction of experienced practitioners." I presume no one will hesitate to accept this palpable truth, but when he adds: "Except in cases where bleeding fibroids may call for the extirpation of healthy ovaries, we might at least require some evidences of the ovaries being diseased before consenting to their extirpation," etc. In the light afforded by the clinical demonstration of the above typical case of Olshausen, and a host of others that might be readily cited, I think this latter statement could be very justly questioned.

At the recent meeting of the American Gynecological Association in our city, you will all remember with what keen and penetrating acumen Dr. Battey, of Georgia, in reply to a question from Dr. Barker, of New York, asking him to state the grounds on which he would advise the removal of the tubes and ovaries, said: * * "I do not require in my cases an absolute diagnosis of disease of the tubes or ovaries prior to operation. It is sufficient for me to know that the general health is broken down by reason of the perverted function of the ovaries, that she is utterly miserable, that there is no reasonable hope of restoration to health by other means, and that there is a reasonable prospect of restoration by removal of the ovaries."

Although to some this may seem a little like equivocation, in my opinion (if so young and inexperienced a man may be permitted to hold an opinion upon such an important question), this is as near to definiteness as we can arrive at present, or from present indications are liable to arrive for a considerable time to come. Hence, in some cases at least, I am inclined to rank myself among those opposing Winckel and a very few others, who require anatomical evidences of disease in the ovaries before their extirpation is considered justifiable. I think that in certain cases, ample clinical demonstration has sufficiently proved the following of this doctrine. As regards the age at which such operations are usually performed, Spencer Wells (op. cit.) says: "It would thus seem that in all the older patients who submit to abdominal section, it is ovariotomy for cystic or other enlargement of the ovary that is done. Out of 171 cases undergoing the operation for hemorrhagic uterine fibroids, 53 were between 30 and 40 years of age, 62 between 40 and 50, and only 9 below 30. The number of cases of oöphorectomy for other causes is comparatively small, and few of them outside the middle age. The limits of our investigations of the diseases requiring oöphorectomy are thus drawn within the narrow compass of 20 years of woman's life, between the ages of 30 and 50. The find here cannot, in the common run of things, be very rich except for fibroids." Further on he says: "The results of myomotomy are deplorable even now, and castration as compared with myomotomy presents us with the striking contrast of a mortality of only 14.6 per cent., a diminution of the tumors, a stoppage of the hemorrhages, and a disappearance of many of the accompanying symptoms. Moreover, as half this mortality has been due to septicæmia, there is here a wide field for surgical enterprise."

DISCUSSION.

Dr. W. P. Chunn said he had never before seen a case of uterine fibroid compli

cated with ascites. His opinion before the operation was that the tumor in Dr. Neale's case was a soft fibroid. The operation, however, proved it to be hard. One reason for his considering the growth a fibroid was that, although there was a marked rectocele, the uterus was not prolapsed, and he considered that to be due to the growth, which, being large, could not descend within the pelvic cavity, and being attached to the uterus held it in its place. Another reason for considering the tumor a fibroid was that any motion imparted to the growth moved the uterus in a corresponding direction. He did not understand why there was no return of the ascites, unless the incision through the abdominal wall modified the circulation of the peritoneum in a similar manner as when one cuts through the capsule of a fibroid.

Dr. B. B. Browne said in regard to the effect of removing the ovaries causing a diminution in the size of the tumor and arresting the menorrhagia, he could speak of its satisfactory results in one case in which he had removed the ovaries and tubes of a colored woman, aged 22 years, who had been an invalid for several years, and unable to work for her living. The interstitial fibroid filled the pelvis, and had grown rapidly for a few months previous to the operation. Since the operation the tumor has almost entirely disappeared, and the flow has entirely ceased.

In another young woman (white) who had been a chronic sufferer and invalid from severe pelvic pains and dysmenorrhœa, the removal of the ovaries and tubes had greatly improved her condition.

Dr. W. T. Howard said, that as Dr. Neale had referred to him, some remarks from him might be expected. Through the courtesy of Dr. Neale, Dr. Howard exhibited the woman to his clinical class at the University of Maryland. There was evidently a large amount of free fluid in the sac of the peritoneum; and the only question at issue was in regard to the *character of the solid tumor*, the presence of which was equally evident. In consideration of the well-known fact that in the negro race ovarian tumors of any kind are exceedingly rare, and *solid ovarian* tumors in any race excessively rare, while in negroes *solid uterine* fibroids are as excessively frequent, Dr. Howard concluded that, in the case in question, the chances in favor of the tumor being a *solid fibroid of the uterus* were at least in the proportion of 500 to 1. That was about as near being a positive diagnosis as one could ever hope to attain in abdominal tumors—and, it might be added, in almost anything else. It was true that, in eight months, Dr. Howard had removed two large solid ovarian tumors, and, as is usual in such cases, there was a large amount of ascites in both. But this experience was quite exceptional, and Dr. Howard never expected to see another solid ovarian tumor. In 378 ovariotomies, the late Dr. W. L. Atlee had never seen one; Sir Spencer Wells only speaks of having seen two in his immense experience; and, in about 600 ovariotomies, Dr. Keith had never seen one.

Dr. Howard certainly thought that he had left no doubt on the minds of all present in regard to the positiveness of his diagnosis, and he knew that at all events most of them so considered it. On the other hand, Dr. Neale strongly inclined to the belief that the hard tumor was *ovarian*.

After Dr. Neale had removed the ascitic fluid through the usual incision, of about two inches in the median ovariotomy line, and inserted two fingers into the abdominal cavity, he announced that the tumor was certainly a uterine fibroid, and requested Dr. Howard to express his opinion as to what ought to be done. Dr. Howard advised a removal of the ovaries and tubes, as *the operation of election* in such cases. The mortality in this operation is very small. Up to May, 1885, Mr. J. Knowsley Thornton had done it for the cure of fibro-myomata of the uterus eighteen times, without a death; and Mr. Lawson Tait, whose experience in this matter is larger than that of any other operator, states that the entire mortality of the operation is only four or five per cent. And it now well ascertained that, in the great majority of cases, the operation is successful in arresting the growth of the tumor and the hemorrhage also; in many cases the tumor shrinks up, or even entirely disappears. Hence when one or the other must be done, removal of the ovaries and tubes for bleeding myomas should always be preferred, in an immense majority of cases, to the far more dangerous operation of *hysterectomy*. Should Tait's operation fail, as it is now familiarly and rightfully called, then hysterectomy may be done. But whoever intends to do a Tait, should always be prepared at the same time to do a hysterectomy, for it is the opinion of all who have had much experience that it is impossible to determine before the abdomen is opened and the relative positions of the ovaries, uterus, and tubes ascertained by sight and touch, which operation had better be done. Indeed, in some of the hysterectomies done by

Dr. Keith, it was impossible to remove the ovaries and tubes without removing the uterus. So that when an operator begins with the intention of only doing the minor operation, he may be compelled to do the major, and should, therefore, never make a positive promise to the patient as to what he will do. In July last, Dr. Keith informed Dr. Howard in Edinburgh, that among persons suffering from uterine fibroids who had consulted him, he only deemed it necessary to perform hysterectomy in sixty. Of these only seven died, or 11 per cent. This is the best result yet obtained by any operator. Still, Dr. Keith considers hysterectomy a very risky operation. In August, 1884, Dr. Howard saw Dr. Keith remove the uterus in a London cook, aged 46, which had grown to be so large that she could hardly get about, and she could not pursue her occupation, by which she made her living. The catamenia returned every three weeks. The entire uterus, ovaries, and tubes, with seven extra-uterine fibroids were in a bucket in fifteen minutes, but so careful was Dr. Keith in completing the operation, that it lasted forty-five minutes longer. Recovery ensued without an unpleasant symptom. To see Dr. Keith do a hysterectomy is a real revelation in abdominal surgery.

Dr. Neale had embraced in his paper other considerations besides bleeding myomas that may require removal of the uterine appendages. There can be now no doubt that in certain cases of the neurotic class, and especially inveterate cases of hystero-epilepsy, this operation has effected cures more or less promptly. And all must have observed the paroxysms in this malady are proven to be intensified at the catamenial periods. But they are not always induced by, or are in connection with a morbid condition of the ovaries and tubes. Dr. Howard was present at the International Congress in London in August, 1881, and heard Dr. Graily Hewitt read a paper on the exciting causes of hysteria and hystero-epilepsy, in which he reported eighteen cases, and proved that in them the particular irritation most potent in producing the reflex phenomena was flexions of the uterus. Twelve were cases of anteflexion, and six more cases of retro-flexion. In these cases attacks ceased when the uterus was restored to its natural position and retained there by suitable pessaries. All must have observed that in flexion of the uterus pain in the region of the ovaries is a very common symptom, and, on the other hand, we often observe prolapsed and exquisitely tender ovaries without any manifestations of hysteria or hystero-epilepsy. Moreover, Dr. Howard had seen two severe cases of hystero-epilepsy in which the ovaries were removed, and yet no perceptible improvement could be observed in these cases subsequently. One was that of a white woman, operated on by his esteemed friend Dr. Frank West. Long after the operation she was admitted into the University, and Dr. Flannery, then assistant to the resident physician, Dr. West, had informed Dr. Howard that he had been kept up nearly all night in controlling the most violent hystero-epileptic convulsion by administration of chloroform by inhalation and by hypodermics of morphia. The other case was a colored woman, skillfully operated on by Dr. Chunn. This woman was kindly brought before the class at the University of Maryland, and was thought by Dr. Chunn to be entirely cured. But with a candor that did him honor, he subsequently affirmed that the paroxysms were as hard as ever, and the last time Dr. Howard heard from her she was wandering around from one dispensary to another in the city, seeking relief. In one bad case of hystero-epilepsy, however, Dr. Howard had a very fortunate result from removing the uterine appendages. Miss J. H., aged 23, came under Dr. Howard's care in December, 1882. At every menstrual epoch she would lie across the bed with her feet elevated as high as possible on the wall, in a state of profound coma, often attacked by violent convulsions, for from seven to ten days. Curiously enough, blood issued around the umbilicus, and she would often spit out blood from the mouth, which was evidently not coughed up, nor vomited. After trying in vain all means known to him, including dilatation of the anterior flexed uterus, Dr. Howard operated November 19, 1883, and, as stated, effected a perfect cure. She is now a married woman in excellent health. In this case the ovaries were obviously much diseased.

(To be continued.)

—As a tonic in the asthenic type of fevers Prof. Gross advises the following:

℞. Quininæ sulphat., ij. gr.
Tinct. ferri chloridi,
Acid. hydrochlor. dilut., āā xv. gtt.
Tinct. nucis vomicæ, x. gtt.
Syr. zingiberis, f℥ ij. M.
Sig.—This amount ter die.

Instead of the nux vomica $\frac{1}{10}$ grain of strychninæ sulphas may be employed.

EDITORIAL DEPARTMENT.

PERISCOPE.

Hæmoptysis Complicating Pregnancy.

Dr. John W. Martin thus writes in the *Medical Press:*

Mrs. P., æt. 26, nine months married, and supposed to be about four months pregnant, came under my care June 11, 1886. She had always been inclined towards delicacy, and about five years before the present illness she had a similar attack of blood-spitting. On the date mentioned, while out driving, she suddenly commenced to spit freely large mouthfuls of blood. When seen, about twenty minutes after the beginning of the attack, the blood was still coming in large quantities, she looked very pale, and spoke in a low whispering voice. Though frightened, she was wonderfully calm and collected. She described the blood as coming from the right upper lobe of the lung, from a point just below the middle of the clavicle. As far as a very gently conducted examination could make out, this portion of the lung was very dull on percussion, the breath sounds were very harsh, and there was a good deal of coarse crepitus to be heard throughout the whole of the upper lobe on that side. Nothing noticeable at the base of the right lung, or in the left lung, except that the breath sounds were a little roughened. There was no rise of temperature, and the pulse was 84, and not very excited. The tongue was clean, the bowels regular, and a sufficiency of healthy-looking water had been passed. There were no symptoms of a cold or of feverishness present. The skin was perfectly cool to touch. She was, and had been troubled with a slight dry hacking cough. It was about a week before the time, when, in the usual course, had she not been pregnant, she should have the menstrual flow. As far as she recollects her former attack took place about the same time before the catamenia were expected. There was no bleeding from the gums, nor had there been any from the nose. Movement of the right arm was difficult and painful, the pain being felt in the affected portion of the lung. The heart's action was quiet and regular. There were no heart murmurs. Perfect rest was ordered, with cold applications, *i. e.*, iced water cloths, to the chest. Ice was given to suck. All fluid nourishment was directed to be given cold. For medicine:

℞. Acid gallic, ℥iss.
Liq. morph., ℥j.
Infusi hæmatox, q. s., ad. ℥viij.
M. ℥j. every second hour.

When seen later in the day, I found the hemorrhage decidedly checked, but she complained that each dose of the mixture caused pain in the stomach. The mixture was changed for the following pill:

℞. Acid gallic, grs. iij.
Ext. gent. co., gr. ij.
M. Ft. pil. xij.
Sig.—One to be taken every third hour.

June 14. The pills checked the hemorrhage to a very large extent, but not altogether. With the diminished discharge from the lungs, slight epistaxis appeared. The dyspeptic symptoms continued, but to a much milder and more bearable degree. To relieve the latter, ordered—

℞. Sodæ bicarb., ℥j.
Sp. am. aromat., ℥j.
Tr. zingib., ℥j.
Aqua, ad. ℥viij.
M. ℥j. three times a day.

On the 11th of June I had to abandon the pills. The dyspeptic symptoms continued with their use.

On the 16th of June, a fresh discharge of blood took place. Stopping the pills and mixture, I ordered—

℞. Tr. hamamelis, ℥ij.
Ext. ergotæ liq., ℥iij.
Liq. strych., B. P., ℥ss.
Syrupi aurantii, ℥ss.
Aqua, ad. ℥viij.
M. ℥j. every second hour until the hemorrhage is checked.

18th. The hemorrhage controlled. Treatment continued.

20th. With the exception of pain in the upper lobe of the right lung, she felt considerably better. For this pain I prescribed—

℞. Tr. opii, ℥iij
Chloroformi, ℥iij.
Lin. belladonnæ, ℥ij.
Lin. saponis, q. s., ad. ℥iv.
M. Ft. lin. Sig.—"Caution," "poison," external use only. To be well rubbed with very gentle friction three times a day.

21st. There was no hemoptysis. Slight epistaxis continued. I dropped the strychnia and ergot from the mixture, giving the following:

℞. Tr. hamamelis, ℥iss.
Aquæ, q. s., ℥vj.
M. ℥ss. every third hour.

On the 23d of June the whole surface of the body was covered with a profuse red rash closely resembling that seen in scarlatina. There was no fever, nor was there any sore throat, or rise of temperature. Skin was cool, the pulse quiet; the tongue was slightly furred; other symptoms unchanged. Ordered—

℞. Pot. bicarb., ℥j.
Tr. hamamelis, ℥iss.
Aquæ, q. s., ad. ℥viij.
M. Ft. mist. ℥j. every fourth hour.

For the skin irritation I gave the following lotion:

℞. Hyd. bichloridi, grs. x.
Sp. vin. rect., ℥iss.
Morph. mur., grs. iv.
Glycerinæ, ℥j.
Aquæ, q. s., ad. ℥x.
M. Ft. lotis. Liq. "caution." Ext. use only. To be applied as required by means of a piece of sponge.

26th. Rash disappearing; irritation allayed. The only appearance of hemorrhage now was a slight staining of the sputa, and very slight epistaxis. The sputa presented a rusty tinge, bright in color, careful examination showing there was no connection between the epistaxis and the staining of the expectoration. The upper portion of right lung clearing. Resonance returning; coarse crepitus no longer to be heard. Ordered tincture of iodine to be painted only in successive patches over the affected lung.

July 12th. Still slight hæmoptysis, and recurrence of pain and discomfort in the clavicular region in the right side. Ordered a small blister, 1½ inches in diameter, to be applied just below the centre of the clavicle for 4½ hours.

13th. The blister acted nicely, and gave great relief, improvement becoming steady from this day forward. The relief afforded by the blisters was so marked and noticeable to the patient herself, she begged a repetition of them when and wherever pain was felt. Four such blisters were applied, some in front of, some behind the shoulder, and all with well-marked benefit. She soon became able to get up and walk about a little without inducing fresh hæmoptysis. The affected portion of the lung rapidly cleared up, and her further progress was of so satisfactory a nature, that, on the 26th of July, she was enabled to return home, bearing the journey from Sheffield to Beverly without any ill effect.

There are not many remarks to be made on the case. Obstinate bowels had to be contended with, but were satisfactorily regulated by means of castor oil, compound liquorice powder, and Hunyadi water, according to circumstances. The action of hamamelis in this and other cases in which I have tried it seemed very satisfactory. My sole regret in the management of the case was that blisters had not been used at an earlier period. I had strongly recommended them at the outset, but the patient's husband was so decidedly averse to their use, I had to refrain. I have the greatest confidence in the use of blisters, used only to obtain their stimulant action by application for short periods of time, in the treatment of neuralgic pains, especially cardalgia, also in cases where there is effusion of serum into either the pericardial or pleuritic sacs, or where there is old-standing congestion of the lungs. The aim should be to secure the mildest blistering effect possible. If this is attained, the blistered surface soon heals without much discomfort to the patient, who, losing the dread of blisters, is ready to submit willingly to their repetition, and the effect, though mild, accomplishes all that we have in view. I believe also that such a use of blisters is the most effectual method at our command for dealing with those cases in which, from loss of tonicity in the heart-walls, there is the tendency to inefficient action and dilatation. Many such cases have come under my notice, which have done well under this treatment. I am not advocating, nor am I a believer in the old method of applying blisters for eight to twelve hours. Such applications did serious damage to the skin, often inducing sores most difficult to heal, and altogether depressing and weakening in their effects.

Phytolacca Decandra in the Treatment of Bronchocele.

Dr. J. D. Ely thus writes in the *Medical Age:*

Of course it is taken for granted that notice of any agent that is superior to iodine, biniodide of mercury, and other time-honored and much-used remedies in the treatment of bronchocele, and especially one that is free from the deleterious effect—such as iodism, derangement of the stomach, etc.—as frequently noticed and regretted of them, will be received by the profession with interest and profit.

Therefore it is with pleasure that I offer a few facts in regard to phytolacca decandra, which, I believe, is as near a specific for that troublesome disease as we have for any other.

In doing so, I wish it understood that I

have tested thoroughly about all the remedies recommended by leading authors, and after comparing the effects and results of phytolacca with them, much prefer it.

It has been a favorite remedy with my father more than twenty years in the treatment of all glandular diseases.

It has never failed, in his hands, to cure all cases of bronchocele, curable by any means, upon which he has used it, and he has, because of his success, had more than the usual number to treat.

Before giving the report of a case illustrating its use which I select from a number I have treated successfully during the past two years, it is important to note that much of the tincture and fluid extract of phytolacca on the market is worthless, and I have, from necessity rather than choice, prepared most of the tincture which I have used.

I would advise those who have given phytolacca a trial and condemned it, and any who may try it and not get satisfactory results from the article purchased, to prepare their own tincture.

The following method has always given us a reliable and satisfactory article; but before it I may note, for the benefit of those not acquainted with phytolacca, that it grows in abundance in nearly all parts of this State, and is known to most farmers by its common name, "poke root."

Procure the fresh roots, and, after washing them clean, slice and put to dry where they will get the sun, till the water is as nearly dried out as is possible, then pack in a percolator—a fruit jar will answer—and cover with absolute alcohol, full strength.

(It is probable that many manufacturers of it do not get a good article because they use old, dry roots, and diluted alcohol as the menstruum.)

Let it stand at least fifteen days, press out, filter, and it is ready for use. Dose, from three to ten drops.

It should be borne in mind that it acts slowly, and is designed to, and in the doses recommended, as experience has proven, that in so using it the specific alterative effect desired is more safely and satisfactorily obtained.

Recent cases yield readily to the remedy, and are cured in from one to three months. Difficult cases of long standing, of which the following is a sample, will need treatment for a year or more:

Lizzie M., aged 16 years, consulted me June 17, 1885, for treatment of a bronchocele, the first appearance of which was noticed eight years previous. On examination, I found both glands and the isthmus involved, and so great was the enlargement that the circumference of the neck measured nineteen and one-fourth inches.

It was more uniform than generally seen, was very hard, and so tightly filled the skin that it could not be moved. Pressure upon the laryngeal nerve was so great that the patient wheezed as if suffering from asthma, and could not walk rapidly because of the interference with respiration.

She presented the characteristic appearance peculiar to scrofulous diseases, and there was history of similar troubles among the relatives.

Bowels were regular, kidneys all right, and menstruation, which had been properly established at 13 years of age, was regular, and had always beeen so.

I may add here that the menstrual irregularity mentioned by some authors as always to be noticed in these cases, has not been found, by me, to exist in any I have treated, and I do not believe it is common or that the disease is, in any way, connected with disease of the reproductive organs, as claimed by some.

Recognizing this as a most difficult case, my prognosis was unfavorable; but the patient being anxious to try treatment, I consented to give it, and prescribed the following, which was used for about one year and with success:

℞. Tinct. phytolac. decand., ℥ ss.
Syr. simplicis, ℥ iijss.
M. Sig.—One teaspoonful in water 3 or 4 times a day.

Also—

℞. Ferri dialyzati ℥j.
Glycerini puris.
Syrup simplicis, āā ℥iss.
M. Sig.—One teaspoonful in water after each meal.

Ordered applications of the tincture to the glands night and morning, to be diluted with pure rain water if it caused much irritation—as it will sometimes—and, if necessary, to discontinue it for a few days, and to take plenty of outdoor exercise.

The only change noticed the first two months was that the glands had softened slightly. After that they decreased in size quite rapidly, and the improvement was marked in every respect, continuing till the neck became normal in size, the difficulty of breathing disappeared, and the patient considered herself cured, one year after beginning treatment.

She continued the application and tonic for a short time longer, at my request, how-

ever, to make "assurance doubly sure," and to prevent any recurrence—a plan which I have always considered good, and recommend.

I have under observation patients who were treated with phytolacca successfully eleven years ago, and, so far, the cures are permanent.

In one case only has there been any return of the trouble, and that was due to the patient considering herself cured and stopping treatment too early.

It is very important, I think, to always use a tonic when giving an alterative, and I never omit it.

I have, in a few instances where there was difficulty in getting the patient to take the separate prescriptions regularly for a long time, combined the phytolacca with the prescription containing the dialyzed iron, apparently with as good results, but prefer to give them singly, and generally do.

Intestinal Lesions Due to the Action of Mercuric Chloride.

Since corrosive sublimate (mercuric chloride) has been so generally used in surgery, and especially obstetric practice, the attention of medical men has been attracted to the different intestinal lesions which have fallen under their notice. A collection of clinical notes demonstrates that mercuric chloride can produce deep lesions in the large intestines. Complete clinical facts may be interpreted in different ways, and have therefore not furnished convincing proofs. Some authors suppose that in cases of parturition the visceral lesions are due to the septic condition existing in the patient, and that the salt of mercury is not a factor. Experimental data, especially those obtained by Prévost's experiments described in the *Revue Méd. de la Suisse Romande*, 1882, indicate that visceral lesions often result from the effect of corrosive sublimate. Similar lesions to these observed in patients were experimentally provoked in animals; ecchymosis and hemorrhage were observed, but neither gangrene nor ulceration. MM. Charrin and Roger used an aqeous solution of corrosive sublimate at 1 per 1,000 and 1 per 4,000, which was injected under the skin or into the veins; this last method requires smaller doses. After injecting 2 milligrammes under the skin of a guinea pig, weighing 500 grammes, several ulcerated areas were observed; an injection of 5 milligrammes given in the course of eighteen days, or 3 milligrammes in six days were powerless; these animals experimented on by MM. Charrin and Roger did not present during lifetime any important symptoms of intestinal lesion; they grew thinner, had albuminuria, but rarely diarrhœa, and never intestinal hemorrhage. When the dose of mercuric chloride was weak, the animals did not succumb to it; they were killed at successive periods in order to follow the evolution of the lesions; it was observed that these were localized in the large intestines, and especially in the ascending colon and cæcum. Sometimes the ileo-cæcal valve and the terminating portion of the ileum were attacked. The earliest lesion consists of small spots of hemorrhage dotted about on the intestinal mucous membrane of the peritoneum, the omentum on the outer surface of the kidneys, and especially on the pulmonary tissue. At a later stage these spots of hemorrhage become small ecchymoses, presenting the aspect of lines parallel to the axis of the intestines, varying in length from three to four centimetres; later on, ecchymosis is more extended, and the central portions slough away; a black eschar is formed, which gradually falls off and leaves an ulcerated spot; contiguous portions of peritoneum sometimes present inflammation. Intestinal perforation has never been observed by these investigators. The principal lesion which occurs consequent on administering corrosive sublimate is apparently intestinal hemorrhage which causes the intestinal mucous membrane to become slightly swollen, and thus disables it as a factor in the process of nutrition. This hypothesis is verified by microscopical examination, which revealed the presence of spots of hemorrhage in the aureolar tissue; the mucous membrane becomes detached and sphacelous without any glandular change taking place, as might be supposed would result from the elimination of the poison. These facts in experimental physiology, applied to human patients, indicate that a dose of 24 centigrammes of corrosive sublimate is necessary to produce intestinal ulceration in a man of 60 kilogrammes or 60 centigrammes given in the course of five days, but the result is not constant unless the sublimate is given in hypodermic or venous injections. It remains also to be proved that the human susceptibility to the influence of this substance is the same as that of the lower animals, and some clinical facts suggest that smaller doses of corrosive sublimate act on the human subject and provoke intestinal lesions; nevertheless, MM. Charrin and Roger do not consider that the possibility of these accidents ought to be urged as a reason for proscribing the use of corrosive sublimate as an antiseptic agent.

A Case of Fracture of the Skull.

Dr. E. Bruno Zinke reported the following case before the Cincinnati Academy of Medicine at their meeting October 18, 1886:

The patient, a man æt. 40, was hit on the head with a large-sized beer-glass with such force as to break in the skull. He was stunned, but did not lose his consciousness. The wound bleeding very profusely, he endeavored to stop it. Feeling the rough edges of the bone, he mistook it for pieces of glass, and tried to remove it. The pain was too great, and he desisted. The doctor found him two hours later exhausted and pale from loss of blood. Examination showed a large, deep, and gaping wound, the soft parts considerably contused and lacerated. This wound extended from the left frontal eminence backwards and inwards, touching the median line. It was about 2.5 inches long. The fracture had the same direction, not quite so long, its sides markedly depressed, the edges separated from each other, leaving the dura mater plainly visible, but unbroken. The hemorrhage ceased, the wound was cleansed, the edges of the soft parts approximated with a silk suture, and an opening left for pus or serum to escape. The wound healed by first intention, and the patient recovered without an untoward symptom, being discharged at the end of five weeks.

The treatment was cold applications for three weeks, and an ointment of salicylic acid and vaseline gr. j to ʒj. for two weeks. He returned after he had worked a few days, complaining of headache and dizziness, probably due to excitement and drink. He was relieved by a few doses of bromo-caffeine. He came back again in about two weeks, complaining of pain in both sides under the ribs, general malaise, loss of appetite, coated tongue, diarrhœa, no fever, pulse normal. He was put on nitro-glycerine gtt. j, one per cent. solution four times daily. Three days later he reported himself well, and returned to his work. He is addicted to drink, principally beer. He took part in the Franco-German war from beginning to end, suffered innumerable hardships, but was never on the sick-list.

The case is interesting on account of the few symptoms that presented after such extensive injury. Surgical interference was not to be recommended as long as the patient was doing well, because cirrhotic liver was suspected. His temper is very irritable since the injury, and he complains of shooting pains through the brain towards the region of the wound during change of weather.

Dr. R. W. Stuart thought from the patient's gait there were some ataxic symptoms. Dr. Zinke assured him there were none.

Dr. H, L. Taylor recommended the doctor to keep a watch on his patient, as he feared the advent of epilepsy.

Manaca in Muscular Rheumatism.

Dr. Thomas P. Gary says in the *Medical Age:*

I have treated quite a number of cases of muscular rheumatism, which is getting to be very common in this country, and in no instance have I had any reason to complain of the results obtained from the use of manaca.

It will only be necessary to give a history of one case, for its effects have been uniform throughout. The patient had been a sufferer for quite a number of years, and had tested the talents of distinguished physicians without receiving any material benefit. He had suffered much from malaria for four years, and physicians differed as to whether he had any syphilitic complication. If there was, it most probably was the result of vaccination during the war, as he presented no evidence of having contracted it in the usual way.

He was out shooting one day, during a small rain-fall, and although he did not get very wet, a pain of a neuralgic character began in the region of his right nipple, and he became feverish and quite nervous. Subsequently he was under treatment by physicians, but was often annoyed by neuralgic pains in various portions of the body, but more particularly in the muscles of the chest and back, occasionally in legs and arms. Any extra exertion produced them, though subacute. He was subjected to constitutional treatment of iodide potassium and mercury, without any material benefit, for several years, and finally came under my observation. I prescribed fluid extract of manaca in 35 and 40 drop doses three times a day. This he continued for two months, and the improvement was gradual and permanent, and to-day he expresses great confidence in being entirely cured. The duration of this "disease," the failure on the part of other physicians to relieve with standard medicines his condition and the great improvement under the use of manaca, certainly should encourage us to give this remedy further trial in these cases.

—A German anatomical society has been founded, with Prof. Kölliker as President and Prof. Bardeleben as Secretary.

Reviews and Book Notices.

BOOK NOTICES.

Outlines of the Pathology and Treatment of Syphilis and Allied Venereal Affections. By Hermann von Zeissl, M. D., etc. Second edition. Revised by M. von Zeissl, M. D. Translated with notes by H. Raphael, M. D., etc. Pp. 402. D. Appleton & Co., New York, 1886.

Prof. Zeissl was one of the professors at Vienna, and in that medical centre had a well-earned reputation for his acute and masterly studies of specific disease. The results of these are presented to English-reading physicians in the volume before us. The topics discussed are gonorrhœa, soft chancre, and syphilis, the bulk of the treatise being devoted to the last-mentioned, as we might expect.

The translation, while generally satisfactory, might, in places, be improved. The formulæ are often incorrect in their Latinity. The prominence given pathology seems excessive compared with that concerned with the strictly clinical aspects of the maladies under discussion.

To counterbalance these blemishes, we have an excellent discussion of the more recondite and obscure symptoms of visceral and constitutional syphilis, and a clear and able classification of syphilitic symptoms. While perhaps the work is not such a one as will best suit the general practitioner, all who make a special study of this class of diseases will find it of great utility.

A Treatise on the Principles and Practice of Medicine. By Austin Flint, M. D., LL. D., etc. Sixth edition. Edited by William Welsh, M. D., and Austin Flint, M. D., etc. 1 vol. Pp. 1160. Philadelphia: Lea Brothers, 1886.

The continued popularity of this treatise has been merited both by the conscientious labor expended upon it by the author, and by the broad and scientific spirit with which all mooted questions are handled.

The death of this distinguished physician last March left this edition in a forward stage of completeness, and the editors who undertook the task of continuing the revision and seeing the volume through the press had but little to do beyond the proof-reading. Dr. Austin Flint, Jr., has added a preface, in which he communicates an interesting appreciation of his father's methods of writing and the increasing desire he manifested to learn and to teach the truths of science, no matter whether they conflicted or not with doctrines which he himself had taught previously. This is the only proper spirit, but too often the petty fear of acknowledging one's self in the wrong impels men to take the opposite course.

The plan of the present edition is not in the main altered from that of previous ones. There has been, however, considerable rearrrangement of minor topics, and a number of entirely new articles have been brought forward. These treat of the bacterial origin of disease, syphilitic disease of the lungs and brain, a number of paragraphs on diseases of the spinal cord, on milk sickness, pathology of fever, etc. Various new engravings have been introduced, and all matter in any way obsolete has been rigidly omitted.

A Treatise on the Practice of Medicine. By Roberts Bartholow, M. D., LL. D., etc. Pp. 988. Sixth edition. D. Appleton & Co., 1886.

The large number of readers who are already familiar with this work will be glad to learn that the present edition has been carefully revised by the author, considerably enlarged, and is intended to include all that has in the most recent period been added to practical medicine, especially in its clinical horizon.

The author felicitates himself on the large sales obtained for the previous editions, and there is no reason why the present one should not continue to gain in the opinion of many. What doubtless lends the volume one of its special attractions to these is the authoritative expressions which are frequent in its pages on subjects where the reader might be left in uncertainty elsewhere. This remark applies both to pathology and treatment.

The fullness with which therapeutics are taught stands in noteworthy contrast to the majority of treatises on practice. This, too, is undoubtedly a feature which will be agreeable to numerous purchasers. Some seeming excess of conciseness in certain portions is explained by the fact that this is but one volume of a series proposed by the author, which will cover the whole domain of special pathology and therapeutics.

—Prof. Da Costa says one of the most efficient means of preventing the "pitting" of small-pox is the application of—

℞. Hydrarg. chloridi corrosivi, gr. j.
Aquæ, f ℥ iij.
M. Sig.—Apply by means of a camel's hair brush.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

MEDDLESOME MIDWIFERY.

We have heard considerable on this subject, but the best illustration came to us a few days since. In conversation with a monthly nurse, we were told that in lecturing to his class of nurses, an obstetrician of no mean repute was wont to lay down the following rules: The patient should be fed every four hours, the baby should be put to the breast every two hours, and the vagina should be syringed out every three hours. We were led to calculate what all this fuss meant. Feeding every four hours means six times in twenty-four hours, nursing every two hours is twelve times, and syringing every three hours is eight, making a total of twenty-six operations in twenty-four hours. In this schedule the teacher unfortunately neglected to mention any time for the patient to *rest*, from which we are led to infer that he considered rest a matter of little importance for the lying-in woman, though in this particular we fear that our readers will not unanimously agree with him;—and he also forgot to mention that his obstetrical fatality was not very low.

Such directions we must characterize most forcibly as "meddlesome midwifery." As a rule, syringing is not required, but it is a universal rule that rest and quiet are essential to a happy restoration. The baby should be nursed every two hours, at first, and the four-hour rule for feeding the mother is very good during the day, but we do not think it would be wise to disturb her at night, though if awake and hungry a glass of milk and a cracker will come in well.

Remember that the doctor does not restore the parturient woman to her normal condition; nature alone can do this, and unless she is failing to do her work properly the doctor had better keep his hands off.

INFECTIOUS OR TRAUMATIC PNEUMONIA.

The opponents of the theory that acute pneumonia is always an infectious disease, used to contend that in those cases where a trauma was suddenly followed by acute inflammation of the lung, an infection could surely not be thought of. It has been maintained on the contrary, that in cases of trauma either an injury to the parenchyma permits the entrance of the specific micrococci, or the minute hemorrhages that occur in the lung in some cases of brain lesions form the starting-point for the development of the microbes.

A. Petit reports the case (*Gaz. Hebd. de Méd. et de Chir.*, 1886, No. 7,) of a man æt.

24, who received, in consequence of a fall, a severe contusion of the right thorax; immediately after right-sided pneumonia developed, which gradually changed to a typhoid state, and caused death after a fortnight. Not only intra vitam in the characteristic sputa, but after death in the inflamed portion of the lung, pneumococci were found in astonishing numbers. P. believes that in this case the rupture of alveoli made the entrance of the cocci possible.

As pneumonia may occur at any time of the year, though more frequent at certain seasons, we can draw the conclusion that the air, especially in large cities, always contains more or less pneumococci, which, however, evince a special vitality in peculiar conditions of the atmosphere. Like in other microbes, these cocci develop in the lung only under favorable circumstances. This theory, which experience has proved a certainty, explains all the varieties of lobar pneumonia.

ACUTE MULTIPLE GANGRENE OF THE SKIN.

Cases of acute multiple gangrene of the skin are rare, and it is not to be wondered at when the views of authors regarding the disease greatly vary. Prof. Doutrelepont, of Bonn (*Tiert. f. Dermat. u. Syph.*, 3, 1886), had recently a case of that kind under his observation. From the course of the disease he believes that it is nothing but herpes zoster that continually relapses. It is admitted that the latter disease is due to inflammation of a nerve, which usually starts in the superficial branches of it, and which induces a disturbance in the innervation of the skin, and therefore a morbid change in the nutrition of the latter.

In favor of D.'s view was the fact that the multiple gangrene developed shortly after the patient, who was a strong and vigorous servant-girl, had run a needle under one of her finger-nails. In the immediate neighborhood of the injury a number of gangrenous spots showed themselves, and thence they rapidly spread towards the centre. First the dorsal surfaces of the hand, then the forearm, the shoulder and upper arm, and the back of the trunk on the same side were affected, while the portions of the skin first attacked continually developed new crops. Only after several months the disease reached the middle line, but when it had passed that, it spread with great rapidity all over the body. About a year after the beginning of the disease head and face became similarly affected. During that time there occasionally were periods when the complaint seemed to have come to a stand-still, but soon new crops developed, and the disease again progressed, always following the same course.

Otherwise, the patient evinced no symptoms of any disease. The urine was normal. So were all sinew reflexes. The mortification attacked only the epidermis, and rarely penetrated deeper. There was was no itching nor any other sensory disturbance connected with it. At the time of the report, sixteen months after commencement of the complaint, no cure had yet been established, but the malady seemed to progress slower and with less virulency.

Microscopic examination of the nerve fibres in the parts affected, gave no result. Though micro-organisms were carefully looked for, none could be found. The small gangrenous patches, when healed, left ugly marks, similar to those of small-pox, but deeper and more irregular in outline. They were sufficient utterly to disfigure the once handsome face of the patient.

Notes and Comments.

An Unusual Case of Post-Partum Hemorrhage.

On February 1, Mrs. S., a strong, healthy, well-formed woman, was confined with her first child. The labor presented no complications, and was completed within reasonable time under the influence of a moderate quantity of chloroform. The placenta came away entire, and the lacteal secretion was quite normal. The patient went on all right until the fifth day, when Dr. Williams was sent for to come at once, and he found the bed filled with blood and abundant hemorrhage still taking place, the patient being almost collapsed. Two drachms of ergot had already been given by the nurse, and ice applied to the abdomen. The uterus was distended to the size of an eight months' pregnancy. A hypodermic injection of a drachm of the fluid extract of ergot was promptly given, and the uterus was emptied of the clots. Subsequently another hypodermic injection of ergot was given, and constant pressure maintained on the uterus, which had the effect of putting a stop to the hemorrhage. The patient ultimately made a good though protracted recovery. No cause could be discovered to account for the hemorrhage; but it was elicited that the patient had been in the habit for some weeks previously of inducing sleep by inhaling chloroform liniment, and that latterly she had used

as much as eight or ten ounces every night. On the night in question, she had used the inhalation with unwonted freedom, and at one o'clock it had affected her so profoundly as to produce this alarming attack of hemorrhage. The patient was induced to abandon the habit, and the hemorrhage did not recur. Dr. Williams (who reports the case in an exchange) expresses himself as very well pleased with the prompt and effectual action of the ergot, to the influence of which he attributes the early arrest of the hemorrhage.

Case of Gangrene of Both Legs in a Young Girl, Due to Arteritis.

G., aged 18, first seen on August 17, 1882, had been suffering such severe pain in both legs and feet, as to deprive her of all sleep, and to reduce her to a state of collapse in the morning. The pain was evidently in the course of the femoral arteries and their branches; and pressure over them could not be tolerated. Both feet were cold and tallowy-looking, the toes already having a bluish appearance, and giving the impression of commencing gangrene. There was no cardiac disease. She had been out to tea the previous afternoon, and been taken with the severe pain on returning home. Stimulants, abundance of nourishment, and opium, were given, and she rallied. The gangrene, however, spread on the right side to Scarpa's triangle, and to the knee on the left, the pain along the course of the arteries being a most marked and distressing symptom. The toes were shrivelled and dried up; blebs, however, formed higher up the legs. Towards the end, a sharp attack of bronchitis, with a considerable rise of temperature, developed, and death resulted from exhaustion. She was always an extremely anæmic girl, and had been under treatment several times for anæmia. She had never had any serious illness. She died on September 12th. The father drank, and the mother was both nervous and anæmic. In the early part of the attack, whilst the legs were dark looking, they were noticed one morning to have assumed a bright red tint, but were quite cold; the patient declared, however, that she felt something running in them. The diagnosis of arteritis (made by Dr. M. G. Biggs, *Brit. Med. Jour.*, Oct. 9,) was based on the absence of any other cause, and the presence of marked and severe pain along the course of the arteries, with tenderness, most acute on pressure. The bronchitis was looked upon as probably secondary to some embolic plugging.

On the Absorption of Red Blood-corpuscles in the Respiratory Tract.

The researches of Pubini and Giuffre upon numerous animals were made in the following manner: The heart of a frog or of a toad was laid bare, and a wound was made at the apex. As the blood issued, it was received in an 0.75 per cent. solution of chloride of sodium, the proportion being 20 parts of blood to 80 parts of the saline solution. This mixture, after being strained, was slowly injected into the trachea of a guinea-pig or of a rat. After the lapse of from five to fifteen minutes the animal was killed by destroying the medulla oblongata. The chest was speedily opened, and the afferent and efferent vessels of the heart tied. The heart was then removed, and its external surface carefully and repeatedly washed with the saline solution. The organ was then opened and its contents examined. Even in the observations made within five minutes of the tracheal injection, some batrachian red blood-corpuscles were found in the midst of the innumerable corpuscles proper to the animal itself. In like manner, the blood of the rat or of the guinea-pig was injected into the trachea of the frog or toad. From five to seven minutes afterwards the animal was killed, and corpuscles belonging to the mammalian animals were always found. The authors hope that these facts may serve as the basis of a new method of transfusion.

Gelosine.

At a recent meeting of the Société de Thérapeutique, of Paris, M. Guérin read a paper on gelosine, a mucilaginous substance extracted from a Japanese alga, which is sold in the form of dry whitish leaves. Gelosine is an excellent base, mixing easily with all pharmaceutical substances, soluble in alcohol and water, and in acidulated or alkaline water; it served as a medium for salts, powders, and different tinctures, and was of great utility in preparing suppositories. Gelosine gradually contracts and expels the water and medical substances it contains, which are thus spread over the surface of wounds or cavities, in which it is placed in any form. Gelosine thus gradually regains its original volume, but can be used more than once for the purposes cited above. Gelosine, therefore, appeared to be preferable to liniments and ointments. M. Guérin showed specimens of cylinders and slabs of gelosine, containing camphor, creasote, sulphate of zinc, cocaine, tincture of belladonna, iodoform, corrosive sublimate, carbolic acid, and

coal-tar. In order to use gelosine as a medium, the quantity required should be immersed in its weight of hot water; the therapeutic agent is then added and incorporated. When the mixture becomes as thick as syrup, it is then poured into moulds. These operations were completed in a quarter of an hour, and the expense was slight. Sterilized gelosine might be used in bacteriological research.

The Use of Ice-water Enemata in the Treatment of Diarrhœa.

This means of treatment has frequently been adopted in cases of collapse occurring during the diarrhœa of young children at the Birmingham (England) General Hospital. In cases occurring outside hospital practice this method is not generally known. Being convinced of its utility, Dr. Robert M. Simon records his experience.

Ice should be dissolved in water, and from two to three ounces injected. The immediate effect is commonly a quiet sleep, and improvement in the collapsed condition. Subsequently, the effect upon the diarrhœa is also good, and it will rarely be found necessary to repeat the enema. Internal treatment may often have to be continued, but he has no doubt that the life of many a collapsed child has been saved in this way. No reference is to be found in Ringer's *Therapeutics* to this method of treatment, but doubtless it is known to many of the older practitioners, though its disuse has led to its being unknown to the younger members of the profession. It appears probable that it acts by an astringent effect on the loaded vessels of the intestines, and so at the same time warming the exterior of the body, and diminishing the materials for the intestinal flux.

It has sometimes been found expedient to give a few drops of brandy about the time of injection; but, in his experience, no depression or bad effect has ever resulted.

A Case of Multiple Hemorrhage in an Infant, Followed by Jaundice.

The infant was born at term, of healthy and well-formed parents, after a normal pregnancy and labor. The day following birth, copious intestinal hemorrhage was noticed, and a mixture containing bismuth was given, the hemorrhage then ceasing. On the fourth and fifth days, the infant lost a great deal of blood from the mouth and nose, but less than from the intestines. The appearance of the child was fairly satisfactory, and it took the breast well. On the sixth day, numerous subcutaneous extravasations showed themselves, mostly in the neighborhood of the knees and elbows. The detachment of the umbilical cord also gave rise to some oozing. The child was placed in cotton-wool, to avoid the formation of fresh ecchymoses. On the eighth day, there were more ecchymoses and epistaxis, and the infant showed signs of exhaustion and had a yellowish tinge of the skin. On the ninth day, a smart hemorrhage took place from the site of the umbilical cord, which was only checked with difficulty; it recurred the same afternoon, and subsequently on the following day, when the child succumbed. No *post-mortem* examination was allowed, but the case was diagnosed as one of simple hæmophilia.

Case of Vulvo-rectal Fistula from Violence during First Coitus.

The patient, a young woman of 22, attended the Gynecological clinic of the Philadelphia Dispensary with the following history: Previously to her marriage, eighteen months ago, she had been a perfectly healthy woman. From the first attempt at sexual intercourse she dated all her trouble. The pain was so severe that she almost fainted, and the act was followed by hemorrhage, which persisted for a month, and was accompanied by the passage of fæces and flatus per vaginam. Every repetition of the sexual act was followed by renewed bleeding, and even at present intercourse was extremely painful. There was entire inability to retain flatus and fæces. On examination, a rent was found opening into the rectum just within the vulva, large enough to admit two fingers. Inspection showed a perfectly intact crescentic hymen, of moderate thickness, and with a small opening anteriorly. Dr. Price operated by freshening the edges of the tear, loosening the hymen from its attachment, and using it as a flap to supply the deficiency of tissue. Shotted silkworm-gut sutures were used; and the closure, after the operation, was complete, and resulted in perfect union.

Anomalous Case of Scarlet Fever.

On September 9, a young girl, aged six, was brought to the surgery of Dr. Whiteway Wilkinson (*Brit. Med. Jour.*), suffering from an itching in the skin. She looked well, and nothing was to be seen but a red rash, which was distinct on the front of the chest and over the scapular regions, extending upwards on to the back of the neck. He could trace

no error in diet nor presence of worms to account for it. He sent her home, and called next day, and very carefully took her temperature, which he found to be normal. He gave her some alkaline medicine, and she went on well, the rash disappearing next day. Her mother told him that she was feverish, and complained of sore throat on August 22, and that she gave her a cooling aperient, which dissipated the attack. On September 20, he was sent for to see a younger child, whom he found to be suffering from a pronounced attack of scarlet fever, the rash well out, and the temperature 103°. On examining the elder child, he found coarse, heavy desquamation on the cheeks and neck. This has continued over the entire surface of the body; the hands and feet are now desquamating.

"Uranostomatoscopia Frenopatica."

Giné publishes an article in the *Independencia Medica*, of Barcelona, on "Phrenopathic uranostomatoscopy," which signifies exploration of the palatine arch to facilitate the diagnosis of imbecility. In every degree of mental deficiency, from "backward children," to imbeciles and idiots, Giné says a depression of fossa, more or less deep, is to be found in the centre of the arch of the palate. The depression, which corresponds partly with the palatine apophyses of the supra-maxillary bones, and partly with the horizontal portions of the palate bones, has its point of greatest depth on that point of the skeleton which is known to all students as the only spot in which the point of a pin may touch five bones, the two supra-maxillary, the two palatine, and the vomer. The supra-maxillary palatine fossa exists normally in early infancy, and is then very perceptible; but if it be very exaggerated, imbecility or idiocy may be certainly prognosticated. The fossa can be simply seen, or can be felt by the forefinger. The depth of the depression corresponds with the degree of imbecility.

Visceral Tabes.

If one were asked the meaning of "visceral tabes," the reply would probably be given, without suspicion of being wrong, to the effect that the term implied a wasting of the internal organs of the body. But, alas, visceral tabes has no such meaning. The origin of the designation may be thus sketched: Locomotor ataxy is called tabes dorsalis, and sometimes plain "tabes;" visceral crises are remarkable symptoms of tabes dorsalis; a case of locomotor ataxy in which the chief features are the occurrence of visceral crises, is termed visceral tabes. Bronchorrhœa, gastrorrhœa, and entorrhœa are the visceral symptoms most marked in a case of "visceral tabes" recorded in No. 117 of *La France Médicale*, by M. Seglas. In addition to the "runnings" from the bronchi, stomach, and intestines, the patient was the victim of profuse perspirations and copious discharges of urine. The patient is a female, aged fifty, whose father died from disease of the spinal cord, and whose two sisters and one brother also succumbed to paralysis. The knee-jerk is lost only on the right side. The ataxy of gait is not marked, but there is inability to walk well in the dark.

Ligature of Arteries.

Probably few subjects have afforded more occupation to the surgical mind than that of the ligature of arteries, and there seems a probability that it will continue to exercise the ingenuity of surgeons for many years to come. The discussion at a recent meeting of the Clinical Society of London, though it did not elicit the opinions of many surgeons, yielded at least a great variety of opinions, for no two speakers appeared to agree in all particulars. The material of which the ligature should be composed, the kind of knot to be used, whether the arterial coats should be divided, whether two ligatures should be employed and the artery divided when deligation is practiced in the continuity of an artery—are all moot points. Mr. Thomas Smith advocated the employment of the clove hitch, as being less liable to slip or to cause ulceration of the artery than the ordinary reef-knot, which has been in almost universal use of late years. The absence of any necessity for division of the internal coats of the artery seemed to be proved by the experimental researches of Messrs. Ballance and Edmunds. Kangaroo tendon does not yet seem to have established its reputation as a ligature to be relied upon in all cases.

A Case of Double Vagina and Uterus.

In a Bulgarian periodical, published by the Varna Medical Society, and called *Meditzinsko Spisanïë*, Dr. Sevvoff, of the Varna Hospital, describes the case of a prostitute, aged 22, who was admitted on account of chronic cervical endometritis, and in whom, on examination, there was found a septum which began, with a semi-lunar edge, just above the entrance into the vagina, and divided the latter into a larger left and smaller

right halves. Each vagina contained an uterine cervix. The right cervix was larger than the left, and had a normal situation, while the left one was bent towards the right side. Two uterine sounds, on their being introduced into the uteri, did not meet at any point. The right sound could be rotated freely, the left one much less so. Within a few days after her admission, the woman menstruated, the blood flowing from both of the wombs.

Eserine in the Treatment of Glaucoma.

At a meeting of the Academy of Medicine, M. Panas spoke in high terms of a new therapeutic remedy suitable to some forms of glaucoma. Eserine, though one of the most active myotics, cannot always be endured, and pilocarpine in some respects is preferable, although less active. The different collyria which are used are either composed of 5 centigrammes of eserine to 5 grammes of water, or of 10 centigrammes of pilocarpine to 5 grammes of water. The improvement is very rapid, but, in order to obtain a cure, one of these collyria must be used for several months. When first used, five or six instillations should be administered in twenty-four hours, afterwards gradually decreasing the application to one or two instillations per diem. Those forms of glaucoma where this treatment has proved beneficial are precisely those where iridectomy or sclerectomy have been inefficacious.

Treatment of a Form of Diarrhœa in Children.

In the *Brit. Med. Jour.*, July, 1886, Dr. James Braithwaite draws attention to a form of diarrhœa in children, usually occurring after weaning, and from that period to four or five years of age, which is characterized by most horribly offensive motions, due probably to the growth of the ordinary bacteria of putrefaction. It may be successfully treated by disinfecting the bowel contents by means of salicylate of iron. The following prescription is suitable for a child two years old: Sulphate of iron, ℈j; salicylate of soda, ℈j; glycerine, ℈iij; water to three ounces. One teaspoonful must be given every hour for twenty-four hours; *i. e.*, until the stools are well darkened: then every three or four hours, with an occasional dose of castor-oil to clear the bowels well out.

The Physiological Effect of Piliganine.

Piliganine is an alkaloid present in lycopodium saururus, commonly known as piligan or pilijan. Dr. Bardet, *chef* of the therapeutical laboratory of the Cochin Hospital, tested the effect of an infusion of piligan, and observed that it acted as an energetic vomitive, and produced general symptoms which indicated that it is not a suitable therapeutic agent. A chemical examination proved that this plant contained a special kind of resin and an alkaloid which M. Bardet calls piliganine. The alkaloid was isolated by M. Adrian, who gave M. Bardet two grammes of chlorhydrate of piliganine. This investigator made experiments with it on a dog, rabbit, and frog, and concluded from the resulting phenomena that piliganine acts as a poison, and that its influence is principally exercised on the nerve-centres, the medulla oblongata, and the pneumogastric nerves.

Easy Method of Distinguishing the Solutions of Carbolic Acid.

In the *Lancet*, August, 1886, Dr. Matthew Hay suggests a plan for ascertaining the strength of solutions of carbolic acid, if there be any doubt. The method consists in adding a saturated solution of pure crystalline sodic chloride to the preparation to be tested. If such a test be added in about equal quantity to a five cent. solution of pure carbolic acid, the mixture becomes milky and opalescent, and the milkiness does not disappear on shaking. If the solution be lowered to 4.6 per cent. (1 in 21.7), the reaction is not obtained unless the temperature of the mixture is below 47° F.; if lowered to 4.5 per cent., the reaction fails unless the temperature is below 40° F. At the ordinary temperature (64° F.) the reaction is not certain unless the strength of the solution is about 4.8 per cent. (1 in 20.8).

Tooth Powders.

Mr. E. M. Tod, L. D. S., Brighton, states (*Journ. Brit. Dent. Assoc.*, p. 511,) that the following formula affords a preparation which destroys the leptothrix buccalis, neutralizes acid secretions, keeps the gums firm and healthy, and is pleasant in use:

℞.	Cretæ precip.,	℥ x.
	Magnes. pond.,	℥ iij.
	Iridis pulv.,	℥ j.
	Sacchar. alb.,	℥ j.
	Tannin,	℥ j.
	Oak bark,	gr. x.
	Saponis pulv.,	℥ ss.
	Otto rosæ,	♏ xl.
	Ol. limonis,	♏ v.
	Carmine,	gr. x.

Misce.

Sciatica Treated by Galvanism.

In the *Lancet*, July, 1886, Dr. W. E. Steavenson gives a short account of sixty cases of sciatica treated by means of galvanism. In the *Lancet*, July 19, 1884, the author published a paper upon the subject, in which he described the mode of applying the current. Out of the sixty cases, thirty-seven were cured; eleven improved only; nine did not remain under treatment long enough for a certain result to be noted; two were still under treatment, and one had a return of sciatica, which was cured a second time. The number of applications needed to produce a cure was about six to eight; some few patients came twelve or fifteen times. The author concludes by stating that the favorable results obtained by him bear out the opinion given by Dr. Stone in his Lumleian lectures.

Action of Anæsthetics on Living Tissue.

At a recent meeting of the Académie des Sciences, M. Marey presented a work by M. Raphael Dubois concerning the action of anæsthetics on living tissues. Claude Bernard believed it to be that of coagulation. M. Dubois's researches led him to suppose it to be that of dehydration; the tissues are dehydrated by substituting the anæsthetizing vapor for water. When plants are exposed to ether or chloroform, water vapor escapes from their surface, which evidently injures their vitality. M. Dubois considers that this fact explains why seed which is moist, and is submitted to etherization, does not germinate, whereas dry seed submitted to the same influence does do so.

Carbolic Acid in the Treatment of Whooping-Cough.

In the *Brit. Med. Jour.*, July, 1886, Dr. Suckling states that he believes carbolic acid to be almost a specific for whooping-cough. The author treated twenty-three patients with glycerine of carbolic acid; twenty cases left off attending after a fortnight, three failed to obtain relief. The dose given was half a minim in peppermint water for a child one year old, increasing with the age. In fifty per cent. ulceration of the frænum was detected.

Treatment of Phthisis by Ergot.

M. Tenneson uses in his wards from 14.2 grammes of ergotine for a sweating hypodermic injection to cure phthisis, administered half an hour before sweating sets in. After the injection an interval of one or two or three weeks must be observed. In one instance only was there failure, but the successes were very numerous. None of the usual remedies, atropine included, are as efficacious in curing sweating as ergot.

Sulphate of Iron in Diarrhœa.

In the *Brit. Med. Jour.*, August, 1886, Mr. Rothwell suggests the use of sulphate of iron in the treatment of diarrhœa in children. The author has used this drug with much success in the choleraic diarrhœa of adults, and thinks that it ought to be used for those cases of infantile diarrhœa where there are offensive stools. Should there be vomiting, it would be better to give the iron by injection.

Toothache Soother.

The following solution is somewhat expensive and rather potent for retail sale, but will be found useful in the operating-room:

℞.	Cocaine (or the hydrochlorate),	xx. grs.
	Morphia hydrochlorate,	v. grs.
	Benzoic acid,	vj. grs.
	Eugenol,	ʒj.
	Alcohol absolute,	ʒj. M.

The Temperature in Belladonna Poisoning.

It is generally stated that, in cases of poisoning by belladonna, the temperature is lowered, or at the least not raised. In nine cases recently observed in Germany by Kratter and Strassman, the temperature was distinctly raised in every instance. If this proves to hold good generally, it would afford one more argument for using belladonna as a stimulant instead of alcohol.

Correspondence.

A Card From Dr. Van Harlingen.

Eds. Med. and Surg. Reporter:

Will you be good enough to correct a misstatement which appeared in a recent number of your journal to the effect that I recommend a certain treatment for tinea tonsurans?

The fact is almost precisely the reverse. I said that I feared the very ingenious compound application would *fail* in practice. It is no invention of mine.

Arthur Van Harlingen, M. D.

[The blame for this error must be laid at the door of the journal from which we quoted it, a reputable journal.—Eds. Reporter.]

Remarkable Injury of the Finger.

EDS. MED. AND SURG. REPORTER:

Under the head, "Remarkable Injury to the Finger," a French surgeon says he had "not found any such case on record." His treatment was unique and bold. I write you to place on record a similar injury that occurred here last spring. Mack Stout, a clerk, 20 years old, was on a box that was on top of a table, trying to let down the store awning. Feeling his support falling, he jumped off to save a fall, when a hook caught his finger-ring. All the flesh and skin were stripped off, some being extruded through the ring at the opening, whence a large ornamental stone had been forced. The young man came to my office, but I was not in. He then went to Dr. John Chambers, who amputated close up. I had the care of the case afterward. (These later particulars are given to show that this was no "hearsay" case.) Three or four years ago I read in a newspaper of a brakeman jumping off a moving freight train, and catching a heavy finger-ring on a nail, and the finger was torn off. Such injuries must necessarily be very rare, but it is well to be on our guard against them.

Yours truly,

WM. B. CLARK, M. D.

2 *W. Market st., Indianapolis, Ind.*

A Peculiar Case.

EDS. MED. AND SURG. REPORTER:

Seeing your editorial "Report Your Cases," I send you the following:

January 20, 1885. Howard S., 8. 9 p. m., desired to urinate, but could not; considerable pain along urethra. Pulse, temperature, digestion, etc., normal. Ordered morphia ⅛ gr. every 4 hours. 12 p. m., violent epigastric pain in paroxysms; vomited in a few minutes, with marked relief of pain.

January 21, 8 a. m. Violent cramping pains about umbilicus occasionally. Bowels not moved since morning of the 20th. Urinated this morning with very little pain. Ordered morphia as needed, and magnesia sulph. ℥ss every 4 hours until bowels moved.

January 21, 6 p. m. No operation; colicky pains occasionally; abdomen tympanitic and tender; nausea and vomiting whenever food is taken. Continue magnesia, and give an enema of oleum ricini, ol. olivæ āā ℥ss, ol. terebinthinæ ♏x, warm water Oss. T. d. until bowels move. Continue morphia p. r. n.

January 22, 8 a. m. Pulse 120; abdomen greatly swollen; no other change. Tr. iodine ♏j, acid carbolic. gr. ½, every 3 or 4 hours. Continue other treatment except magnesia.

January 23, 8 a. m. Pulse 120. Could see no change. No change in treatment.

January 23, noon. No change except one or two very small lumps of fecal matter after enema.

January 24, 8 a. m. Pulse 140. One or two small lumps of fæces after each injection. No other changes. Gave acid hydrocyanic dil. ♏ij. in place of iodine and carbolic acid.

January 25, 8 a. m. Pulse 140. Less vomiting and pain, and a little more fæces.

January 26. Pulse 140. Slight improvement otherwise.

January 27, 8 a. m. Pulse 130. Less tympanites, tenderness, and vomiting; more fæces.

Improved rapidly from this date. Gave an enema once or twice a day for a day or two, then ½ gr. podophyllin, which cleared out intestinal canal pretty well. After that no more trouble. No trouble vomiting after 20th. On 24th and 25th there was great prostration, etc. No abdominal tumor could be detected at any time.

GEO. W. POTTS, M. D.

New Lancaster, Kans.

"Extraordinary Fecundity."

EDS. MED. AND SURG. REPORTER:—

I have noticed several articles on the above subject in your journal during the past year, and while I do not pretend to make a point in regard to the frequency or the labors, yet the case I have in view seems to present some rather remarkable features.

In the earlier years of my practice I was acquainted with a woman, Mrs. S., who was only moderately stout, rather under medium size, who had four children at single births, with an average of thirteen months between. These were followed by two successive twin births, with about the same average intervals, and these by triplets in a little more than thirteen months, at which time she was attended by a young physician who had located in her vicinity. The poor woman, evidently, or I may say apparently, fearing a further arithmetical progression and increase, took sick and died, after I left the neighborhood, before she had time to become pregnant again.

I knew another woman at this same time who had a second child when the first was only nine months and twenty-seven days old.

WM. F. MITCHELL, M. D.

Addison, Pa., November 1, 1886.

Treatment of Strangulated Hernia by Puncture.

EDS. MED. AND SURG. REPORTER:

In your issue of October 30, 1886, I noticed an article calling attention to the treatment of strangulated hernia by puncture.

I wish to say that it has been my practice for several years to introduce my hypodermic needle into hernial tumors, and thus get rid of the accumulated gas. I consider the procedure safe and justifiable in every case where there is evidence of flatus or gas in the tumor, but it is by no means new to me.

D. H. WOOD, M. D.

Quincy, Mich.

NEWS AND MISCELLANY.

The New Anatomical Institute in Vienna.

On October 11 the new Anatomical Institute was opened in the presence of the Minister of Public Instruction and other members of the university. Those of our readers who have profited by the teaching of this justly-famed centre of medical learning will be glad to hear that the facilities for the study of anatomy are now brought into the same state of excellence as the other departments of medical knowledge, and that the building for the use of the coming generation is in every way worthy of the renown of the great university. The institute, which is situated in the Walringer Strasse, about five minutes' walk from the General Hospital, combines all the advantages of modern sanitary construction, in the shape of electric lighting, lifts, and ventilation, with a proper regard to the æsthetic requirements, so that the gloomy half-lighted appearance which is too often associated with the study of anatomy is quite absent. On entering, one finds one's self in a small entrance hall, from which a staircase, diverging right and left, leads up to two spacious lecture-rooms, capable of seating 300 students, and furnished with electric lights. These, with the library and professors' rooms, form the central block, while the dissecting-rooms, four in number, occupy the two wings. Each dissecting-room is large and light, possesses twelve windows, reaching nearly from floor to ceiling, and ten dissecting-tables. The dissecting-tables are oval, made of marble, and mounted on a solid iron pedestal. Around the walls are eight taps for washing hands, etc., and at each end is a lift communicating with the underground rooms, where the bodies are prepared and injected. In the passage, before coming to the dissecting-rooms, are the prosector's room and the students' cloak room. The electric light, with a special arrangement to prevent shadows, is in each dissecting-room. On the second story, above the central block, is a room seventy-two metres long, facing the street, which is to serve as the museum, osteological specimens being placed round the walls, while the centre will be occupied by cases for preserved specimens. In the underground department is contained the machinery for heating and lighting, and the rooms for cleaning and preparing the bodies, as well as the dwelling-rooms for the employees.

Small-pox in Marseilles.

The epidemic of small-pox, which has ravaged Marseilles during the past year, appears to be on the decline; but, during the twelve months, 1,972 deaths have occurred, half the number being children under ten years of age. The disease spread to many of the neighboring localities; in one case, a girl in a state of convalescence carried it from Marseilles, causing eighteen deaths from small-pox, thirteen in non-vaccinated persons. These facts have again drawn the attention of the public to the necessity of enforcing compulsory vaccination. The recent occurrences in Zurich furnish further proof of the necessity of such a law being strictly carried out. In 1881, the mortality from small-pox in Zurich was 7 per 1,000 from general causes; in 1882 there were no deaths from small-pox; in 1883 the number of deaths rose to eight. At that time the partisans of the anti-vaccination league were instrumental in getting the law on compulsory vaccination repealed; the following year fifteen deaths occurred; in 1885 the mortality rose to fifty-two, and this year it has amounted to eighty-five. It is hoped that a law may be established in France to enforce compulsory vaccination and revaccination, and that it will be carried out in all the chief towns of each department.

"Long Runs" on the Stage, and Madness.

The *Lancet*, October 23, says:

We cannot understand how it has come to be thought that the fact of an actor or actress repeating the same part night after night for a lengthened period can be productive of *madness*. No one doubts that the repetition must be wearisome, and if there were no counterbalancing advantages it might be so

irritating as to be mentally injurious; but players, like the rest of the world, are at heart matter-of-fact people, and, as Mr. W. S. Gilbert points out, the fact of a long engagement has the not inconsiderable merit of relieving anxiety. Moreover, the brain is spared the toil of frequent "study" for new parts. The day is left free; and if there be an irritating sameness about the evening's work, it cannot be a very terrible infliction, for even the most elaborate impersonations must come to be almost automatically performed after they have been so repeated as to lose their novelty. The public suffer for these "long runs" because there is "nothing new" to awaken interest; but if the actors suffer, they have their compensation, and we venture to think that, mentally, personally, and relatively, it is adequate.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE TWO WEEKS ENDED NOVEMBER 6, 1886.

Ames, R. P. M., passed assistant surgeon. Relieved from duty at Marine Hospital, New York, N. Y.. to assume charge of Marine Hospital, Vineyard Haven, Mass., November 1, 1886.

Urquhart, F. M., passed assistant surgeon. To proceed to Norfolk, Va., for duty November 4, 1886.

Yemans, H. W., passed assistant surgeon. Relieved from duty at Marine Hospital, San Francisco, Cal., to assume charge of the Service at Galveston, Texas, November, I, 1886.

Wasdin, Eugene, passed assistant surgeon. When relieved, to proceed to New York, N. Y., for duty at Marine Hospital, November 1, 1886.

Williams, L. L., assistant surgeon. Relieved from duty at Marine Hospital, Wilmington, N. C., to proceed to Pittsburgh, Pa., for temporary duty, November 5, 1886.

Perry, F. B., assistant surgeon. Relieved from duty at Marine Hospital, St. Louis, Mo., to proceed to San Francisco, Cal., for duty at Marine Hospital, November 1, 1886.

Death by a Druggist's Error.

The *Boston M. and S. Jour.* very truly says that the fatal mistake of a Haverhill druggist, whereby eighty-eight grains of podophyllin were put up for one dose for a young woman, the sign *ss*, representing half a grain, being mistaken for eighty-eight, the mistake resulting in the death of the young woman, illustrates the folly of allowing young clerks with no preliminary study or preparation to undertake the responsibility of dispensing drugs.

Were the law whereby apothecaries are authorized to dispense medicines as stringent as it ought to be, or were there, in fact, any State statute whereby a man with no fitness for the place is forbidden to sell powerful drugs (and in all foreign countries such protection is given the public, ignorant and incompetent men being excluded from the druggist's office), such mistakes would seldom or never occur. A very superficial knowledge of materia medica would have indicated to the dispensing apothecary that eighty-eight grains of podophyllin was a dose that it would be impossible for a physician to prescribe.

The Influence of Companions in Education.

In the *Brit. Med. Jour.*, October 30, Dr. G. H. B. Macleod says:

"Again, of the many influences which go to mould a man's character, none, perhaps, are more potent than companions. The mutual effect for good or evil thus engendered is incalculable. From the time of Pythagoras downwards, this has been expressed in many ways. 'Show me with whom he associates, and I will tell you his character,' etc. 'He that walketh with wise men shall be wise, but the companion of fools shall be destroyed.' But who are the fools? Well, in the sense now spoken of, they are the libertine, the idle, the skeptic, and those whose coarse and unbecoming conduct repels you. Never associate with a man you cannot thoroughly respect and gain some good from. That is a simple and useful rule. Be master of yourself in all things. 'Keep a conscience void of offense.' It is infinitely easier to avoid the beginning of evil than to renounce it afterwards. Temptation you must encounter. Resisting it strengthens the character as the tempest gives firmness and vigor to the fibres of the oak. Let not the holy temple of your bodies be defiled by any uncleanness. Remember Tom Hughes' advice—'The only thing to do with "wild oats" is to put them carefully into the hottest part of the fire.' A very trifling lapse from virtue may start you on the fatal path. A tiny grain may pollute and intrinsically alter a pure solution."

Cremation in Germany.

Cremation, it would appear, is making great progress in Germany. There has re-

cently been held at Gotha a "Diet" of delegates from the various cremation societies in Germany, as well as several other countries, including Italy, Switzerland, Holland, and America, the last being represented by Mr. Storer Cobb, of Boston, who is at present lecturing in Germany on the disposal of the dead by fire. The Diet discussed and approved the statutes of a general association of societies for funeral reform and optional cremation, and this association was joined by the local societies of Berlin, Potsdam, Frankfort, Darmstadt, Liegnitz, Chemnitz, Heidelberg, Dresden, Leipsic, Hamburg, Vienna, etc. These societies have already their journalistic organs in the shape of two magazines, called *Gesundheit* and *Neue Flamme* (Health and New Flame). The delegates inspected the crematorium at work in the churchyard at Gotha, and they were assured by the burgomaster that the repugnance of many to this form of burial had been completely overcome by the sight of the decorous and befitting manner in which bodies are reduced to dust by the rapid action of fire, and then inurned.

M. Pasteur.

The statistics brought forward by Dr. de Chautemps at the Sorbonne recently were said to show that M. Pasteur had saved the lives of at least 145 Frenchmen. Of 1500 patients subjected to the prophylactic treatment only ten had died, and two of these deaths could be accounted for without supposing the treatment to have been inefficacious. Taking merely the cases that had been under treatment before August 1, in order to allow of the lapse of sufficient time to ascertain the result of the inoculation, it was shown that the number of cases was 1276. At least 80 per cent. of these cases received bites from undoubtedly rabid animals; so that 973 individuals were bitten. It was computed that 155 of this number would have died if they had been left to themselves; and yet there had been but ten deaths. Hence the claim of Dr. de Chautemps that M. Pasteur had saved the lives of 145 of his countrymen.

The Food of Paris.

The annual consumption in Paris of various kinds of food which can be closely controlled by the registers of the *octroi* was during last year 146,825 tons—an increase of 446 tons over the previous year. Of pork, 148 tons had been consumed less, while the consumption of horse-flesh, with a total of 3830 tons, had augmented 337 tons, as compared with 1884; the average price of the last-named commodity is sixty centimes a kilo, while the meat of asses and mules commands about seventy centimes. Of poultry and game, the aggregate consumption was 25,044 tons—a slight diminution as compared with the year before. The quantity of fish, etc., amounted to 25,631 tons—a slight augmentation, more particularly in oysters. The consumption of butter and eggs has fallen off by nearly 160 tons, which decrease, so far as butter is concerned, may readily be accounted for by the greater use of margarine.

Medical Education of Women in Edinburgh.

The reopening of the Extra-mural Medical School on October 20, was marked by the readmission of women to medical education in Edinburgh, after an interval of more than twelve years. The first year's course comprises, as usual, anatomy and practical anatomy, chemistry and practical chemistry. The ladies' class consists at present of six students, most of whom have just passed the preliminary examination in arts held by the Educational Institute of Scotland on behalf of the Colleges of Physicians and Surgeons. The classes are conducted by Dr. Macdonald Brown and Dr. Stevenson Macadam respectively, and Dr. Sophia Jex-Blake is acting as organizing secretary.

An Unnatural Mother.

Visitors to the Weirtz Gallery at Brussels will remember, among the weird and strange creations of that artist's brain, a horrible picture of a woman sitting over a fire and cutting a young infant up into pieces. What seems almost a realization of this in everyday life appears to have taken place in Manchester (England) recently. A woman was taken to the Ancoats Hospital who from her condition was suspected to have been recently delivered of a child, and upon search being made at her house, the charred remains of a new-born infant were discovered in the fireplace.

The Comparative Prospects of Doctors and Lawyers.

The *N. Y. Med. Jour.* says that the struggles of young doctors are hard enough, as few if any of our readers need to be reminded. To those who are inclined to regard their own prospects as gloomier than if they had chosen some other profession, we commend an advertisement that lately ap-

peared in the *Daily Register*, the New York law journal, in which "an experienced attorney" offered his services to any law firm at a salary of five dollars a week.

Absence of Alkaloids in Hot-house Plants.

According to Prof. A. Vogel, plants do not always contain their characteristic alkaloids when grown under other than natural conditions. Hemlock does not yield coniine in Scotland, and cinchona plants are nearly free from quinine when grown in hot-houses. Tannin is found in the greatest quantity in trees which have had a full supply of direct sunlight.

Viper Poison and Rabies.

A writer in *Los Avisos* mentions that a dog which had been several times severely bitten by different rabid dogs, and had shown nosymptoms of rabies itself, had been previously twice bitten by vipers, and suggests the possibility of the poison of the viper having conferred an immunity from rabies.

The Cocaine Habit.

Dr. J. B. Mattison, of No. 314 State street, Brooklyn, writes to us as follows: "If any reader of your journal has met with a case of cocaine addiction, and will send me the fullest details at his command, I'll thank him for the courtesy, reimburse him for any expense incurred, and give him full credit in a coming paper."

Items.

—The German physicians of Philadelphia propose to organize "Der Deutsche Medicinische Verein von Philadelphia."

—A somewhat sudden and serious outbreak of small-pox, the origin of which has not yet been traced by the authorities, has occurred in Brooklyn, and Health Commissioner Otterson has appointed six sanitary inspectors on special vaccination service. An extra force of men has also been assigned to duty on the fumigating corps.

—On the 22d of October, Dr. Alexander Dyce-Davidson, Professor of Materia Medica in Aberdeen University, died suddenly in his class-room. The bursting of a blood-vessel in the head was the cause of death. The deceased was a native of Aberdeen, and was forty-one years of age. He was appointed Professor of Materia Medica in 1878.

OBITUARY NOTICE.

J. G. Richardson, M. D.

Dr. Joseph Gibbons Richardson, who has been called away in the 51st year of his age, was Professor of Hygiene in the University of Pennsylvania, and a member of the City Board of Health. He was born in this city, and graduated from the Medical Department of the University of Pennsylvania in 1862. He was resident physician of Wills Hospital and the Pennsylvania Hospital, and then practiced five years at Union Springs, Cayuga county, N. Y., and while there was vice-president of the Cayuga County Medical Society. In 1868 he returned to this city, since which time he had held the positions of microscopist at the Pennsylvania Hospital, visiting physician of the Presbyterian Hospital, professor of hygiene in the Medical Department of the University of Pennsylvania, secretary of the Biological and Microscopical Sections of the Academy of Natural Sciences, member of the College of Physicians, Philadelphia County Medical Society, American Medical Association, and many other kindred bodies. He contributed largely to the leading medical periodicals, and of the books issued by him the most important was his "Handbook of Medical Microscopy."

QUERIES AND REPLIES.

Eds. Med. and Surg. Reporter:

Wickersheimer's Fluid.

The following is an answer to query in last issue:

The injection fluid of Conservator Wickersheimer of the Berlin Museum, was first used for the preservation of anatomical objects for demonstration, but has since been used for embalming purposes.

The fluid is composed as follows: Alum 100.0; chloride of sodium 25.0; saltpeter 12.0; potash 60.0; arsenious acid 20.0, to be boiled in three litres of water and filtered.

To 10 vol. of the solution are to be added 4 vol. glycerine and 1 vol. methyl alcohol.

Twenty-five hundred grammes of the fluid are said to be sufficient for a medium-sized human cadaver. It is injected in the carotid with a constant pressure apparatus of two metres pressure height, until foam appears above the windpipe. The abdominal cavity must be emptied; a filling of the same with camphor, saltpetre, alum, carbolic mixtures, etc., is, provided the fluid injection is evenly accomplished, not necessary. It is said that Wickersheimer holds secret a still better embalming fluid, which he only uses himself. It seems that the above fluid does not act satisfactorily in all cases.

Oconomowoc, Wis., Nov. 11, 1886.

Poisoning from Oats.

Eds. Med. and Surg. Reporter:

I have a patient who is poisoned by coming in contact with oats, either in the sheaf or cleaned grain; cannot feed a horse with it, or walk past an oat-meal mill, on the windward side, without being poisoned. The eruption takes the form of eczema rubrum; is very severe, confining him to the house for weeks at a time. Many of the various lotions and ointments recommended for the cure of poisoning by vegetable fungi have been tried, but nothing has had any decidedly beneficial influence.

If any reader of this has had a case of the kind and found a remedy for it, I should be only too glad to hear from him.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

DR BUCKLAND'S
SCOTCH OATS ESSENCE

NATURE'S NERVE TONIC AND BRAIN FOOD.

Yielding the most remarkable results in both Functional and Organic Diseases of the Brain and Nerves, especially

NEURALGIA,	OPIUM and MORPHINE HABITS,	SPERMATORRHŒA,
INSOMNIA,	INFANTILE PARALYSIS,	TIC DOLOUREUX,
SCIATICA,	NERVOUS DYSPEPSIA,	MELANCHOLIA,
MANIA,	NEURASTHENIA,	IMPOTENCY.

FORMULA.—Avena or Avenesca, the active principle of the Oat (Avena Sativa) obtained by crushing the grain (dried in vacuo), with pure alcohol, skimming off the fatty scum obtained by ether washing, evaporating to dryness, and then dissolving the amorphous powder (Avena) with boiling alcohol and flavoring. The dried grain is then treated by maceration and percolation from 96 to 144 hours. The final solution is of a 3½ per cent. strength.

☞Most remarkable cures of the OPIUM HABIT.
☞The most active tonic to both male and female SEXUAL ORGANS known.
☞Almost Specific in IMPOTENCY and SPERMATORRHŒA.
☞As a Brain and Nerve Tonic and Restorer of Wasted Energy it is unparalleled.

Put up in 3 oz. bottles. Price, $1.00. For sale in all drug stores.

Lecture.

LARYNGITIS ULCUS SYPHILITICA: KERATITIS SUPPURATIVA ACUTA: STRUMA, PHARYNGO-TONSILLARIS.

A CLINICAL LECTURE BY DUDLEY S. REYNOLDS, A. M., M. D.,

Professor of General Pathology, Hygiene, and Diseases of the Eye and Ear in the Hospital College of Medicine, at Louisville, Ky.

Reported for the Medical and Surgical Reporter by Allen Kelch, M. D.

SYPHILITIC ULCERATION OF THE LARYNX.

Mr. J. N———, sixteen years of age, of good family, a bright, intellectual youngster, whose home is in Frankfort, Ky., makes his appearance this morning pale, emaciated, and articulating with great difficulty.

Beginning at the superior border of the anterior glosso-palatine ligament is a deep sulcus with ragged, infiltrated marginal outlines; illumination shows this sulcus extending on down behind the tonsil to the base of the epiglottis on the right side, cutting off the ary-epiglottic ligament and extending deeply through the cartilage to the upper surface of the right vocal cord.

Applying a mop made of cotton-wool rolled upon a probe and dipped in a solution of carbolic acid, a half drachm to the ounce of water, the ulcer is easily cleaned to the bottom. In the course of this procedure the muscular movement spreads the opening, which seems to have a rope-like cord drawn obliquely across the chasm near the base; this distinctly pulsates, and is unmistakably the common carotid.

The appearance of this ulcer, which the patient says has been forming now for three weeks, is distinctly characteristic of syphilis. Epithelioma does not develop so rapidly, and tuberculous ulceration would present entirely different appearances. If it were tuberculous, the chasm would be occupied by a mass of tough lymph, because the bacillus tuberculosis grows best in lymph, and its first effects are to swell the lymph corpuscles, and by actual increase of contents to rupture the lymph tubes. The exuding mass of lymph from these points of rupture constitutes the primary breach of continuity in the process of ulceration. The margins of the tuberculous ulcer are always œdematous with a grayish mass of exuding lymph overlapping the edges of the ulcerative surface, and no tissue points of granular surface may be seen until after the removal of the contained lymph, which is always very tough and difficult to clear away—in fact, impossible to completely remove without the assistance of some powerful astringent, aided by friction, to disturb the relations of the exuded mass of lymph and the open lymph tubes through which it comes.

In the case of this young man the margins of the ulcer are everted and ragged, presenting a sharp marginal line of inflammatory infiltration intensely red—scarlet, indeed—whilst the ulcer itself contains a species of pus easily cleared out, tending in no way to resist the mop loaded with the carbolized fluid, which is introduced for its local anæsthetic as well as its antiseptic action. The rapid development of the ulceration alone is strongly suspicious of syphilis, whilst the local appearances of the ulcer, which at the base is gray whilst the walls have irregular projecting points of red tissue with an in-

flamed areola, makes a perfect picture of the syphilitic ulcer.

It is remarkable that this ulceration has not invaded the walls of the carotid artery, whilst all the tissues surrounding it are destroyed, as you observe. It seems impossible for any further extension of the ulceration in the larynx to take place here without resulting in perforation, and if the walls of the tube are perforated emphysema will speedily occur, and the patient must then perish. If this process can be arrested at once, however, the chances of recovery may be said to be fairly good.

As the case is very urgent in its demands for treatment, I propose giving him twenty grains of the iodide of potassium in a half glass of water every two hours. The rags which he now wears about the neck are to be removed, and no local treatment or external application made except a spray of ten grains of borate of sodium to the ounce of water, simply to facilitate cleaning the larynx of accumulations which naturally gravitate that way.

Syphilitic ulceration of the larynx is often fatal when its true nature is not recognized in time to prevent perforation. Just how long an artery may resist the action of the syphilitic virus it is impossible to say, I have known arteries to remain exposed three weeks before rupture occurred in cases of epithelioma where the ulceration had extended to all the tissues surrounding it, leaving it fully exposed in its passage across the cavity.

If the iodide of potassium disturbs the renal function in this young man, we shall substitute the iodide of sodium; in fact, it is my habit to alternate the sodium with the potassium salt, and in some cases to rely wholly on the sodium instead of the potassium. I had a case not long since similar to this in many respects, in the person of a prominent young journalist in this city. His physician, knowing he had syphilis, undertook to administer the iodide of potassium when the ulceration set in, but the patient was suddenly seized with all the distressing phenomena of iodinism. In this condition he was sent to me. I began with 20-grain doses of the iodide of sodium in a glassful of water every 4 hours, which he took without difficulty, and in two weeks' time the extensive ulceration of the larynx had entirely healed; of course, the dose had been increased after the first three or four days.

It is astonishing what great differences are sometimes observed in the action of iodide of sodium and potassium. Any form of potassium appears poisonous to some people, whilst others may take in almost unlimited quantities any one of the numerous preparations. The tendency of iodide of potassium to produce interstitial nephritis is not sufficiently appreciated by the profession, I fear. This tendency is always diminished by the use of the iodide largely diluted with water. If the patient has to take 20 grains of the salt he should have it in not less than four ounces of water; indeed twice that amount of water is preferable, and in all cases where iodide of potassium has to be given for the relief of syphilitic ulceration the dose should be progressively augmented and the quantity of water increased, the patient being required to pass his water in a vessel, in order that no mistakes shall occur in determining the quantity passed in 24 hours. If any very considerable diminution in the quantity of urine passed should occur, I should at once proceed to inquire into the character of the urine voided, with a view to either discontinuing the treatment altogether until the kidney affection can be brought under control, or the substitution of the sodium for the potash salt. From a considerable experience with the iodide of sodium, I am satisfied it meets every therapeutical requirement, and is in no respect inferior to the iodide of potassium in the treatment of syphilis, whilst its tendency to disturb the kidneys is far less. Remember, however, that if the patient can take a pint of water at a time, the potash or sodium should be given in that quantity.

[It was subsequently learned that the young man had been led astray, and contracted syphilis in the usual manner four months before. By the fourteenth day following this treatment the ulcer had entirely healed, and he returned to his home greatly improved in flesh and strength, with his voice fully restored.—Rep.]

Case 2. Suppurative Keratitis.

Mr. W., dancing-master, aged 64, a gouty subject, has been suffering with intermittent fever. Ten days ago his family physician sent him to me with an ulceration of the right cornea, the ulcer being small, and lying almost directly in the centre of this structure. It was superficial, presenting a gray base with a small particle of lymph adhering to its lower edge. The eye was painful, and of course morbidly sensitive to light. The pain radiated from the brow through the temporal region, extending at times to the occiput on the right side. After con-

sultation, it was decided he should take five grains of quinine in solution every four hours. He was to have at night one grain of calomel, to be followed in the morning by a Seidlitz powder. Locally a drop of a solution of homatropine — one grain to the drachm of water—was instilled for the relief of pain whenever it became necessary.

Two days later, Mr. W. presented a sad appearance: the lids were tumefied; the cornea throughout the anterior lower half had become gray; a mass of lymph hung from the central portion, which was still ulcerating, and the anterior chamber was almost entirely filled with lymph. This *lymph* in the anterior is frequently called *pus*. A condition similar to that just stated is described in all text-books on the diseases of the eye as hypopion, and the older writers—even some at the present time—advocate paracentesis of the cornea, with a view to evacuating the irritating pus, as it is called. Some have even gone so far as to describe how the endothelial cells from the surface of the iris and the cornea degenerate into pus and fall loosely into the anterior chamber, producing this collection. This is a condition that never exists in the form described; instead of pus this accumulated mass of effused fluid which presents a gray opaline—sometimes yellowish—appearance in the anterior chamber of the eye, is lymph, as may be easily demonstrated. No one will deny who has punctured the anterior chamber for the relief of these affections that this mass is always found in strings, or flakes, or shreds; that the matter is of a tenacious character and comes away in masses—usually in one mass—when it passes outward. It may be completely removed and extracted from its confinement by seizing it with the forceps and drawing it out as you would a clot of blood or mass of lymph from any other situation. Excuse this digression.

Mr. W.'s condition being now somewhat alarming, the homatropine drops were ordered to be used every ten minutes till the pain ceased—this to be repeated at every recurrence of the pain—and five-grain doses of the sulphate of quinine were ordered to be taken *every hour during the day*. Forty-eight hours after this change in the treatment the cornea had cleared up; in four days the entire mass of lymph effused into the anterior chamber had disappeared by solution and absorption. After this the quinine was administered three times a day before meals in the same manner and dose (five grains) up to the present time (ten days from the beginning of the trouble), the eye now being almost entirely free from irritation, and the general condition of the patient vastly improved. I venture to say he may take ten grains every night at supper-time for a week as a precaution against relapse.

Cases of this kind, unless treated in the vigorous manner I have just described, go rapidly from bad to worse, until the cornea sloughs out en masse, and the eye is destroyed. Cases are not wanting where symptoms of meningitis occur at this stage, and death in a few hours or a few days at most comes to the relief of the patient, who in my opinion might have been saved by the timely and vigorous use of the sulphate of quinine. A gentleman so well advanced in years, with a gouty diathesis, so sadly afflicted as Mr. W., affords to my mind a magnificent illustration of the triumph of medicine over disease.

Case 3. General Struma.

J. McK., æt. 28; pale, relaxed tongue; hoarse, husky voice; pulse feeble; skin clammy; respiration 30 per minute, and labored. He is harassed by cough at night, and complains of soreness in the chest. He does not sleep well, has a poor appetite, and for two months past has been troubled with night-sweats; he has been twice rejected for life insurance within the last two years. His mother and sister are said to have died of pulmonary consumption; he resembles his mother in facial expression, complexion, etc., and is thought therefore to be especially liable to pulmonary consumption; in fact, he thinks he is now afflicted with it. His family physician, however, Prof. E. R. Palmer, an expert in physical diagnosis, has not been able to detect any distinctly localized pulmonary disease. The patient is a man of family, and observes correct habits, indulging in no dissipation whatever. For three or four mornings past he has supplied me with the sputum expectorated during the night. Careful microscopical examinations from time to time have been made; no tubercle bacilli have been found. The cervical lymphatics are all enlarged, the tonsils are pale and enormously distended, in fact, they are in contact at the superior extremities. He finds it difficult to swallow solid food, and he says a large quantity of matter flows down from the palate into his throat on rising every morning. The lining membrane of his nose is pale, soft, pulpy, and covered here and there with accumulations of very tenacious lymph. In the pharynx a considerable quantity of pus which, pouring down upon the posterior wall of the cavity, is brought into contact with the air inspired

through the mouth, and dried, presents itself in the form of brown or yellowish-brown crusts. His tonsils have never been subjected to local treatment, though he has used a variety of sprays and gargles. He says he has been eight months under the treatment of a prominent specialist in the city, and that he has taken, he thinks, several gallons of cod-liver oil.

I am glad to be able to present such a case for consideration, inasmuch as it will afford an opportunity to demonstrate a principle in therapeutics, as well as to relieve Mr. McK. of a troublesome and somewhat grave affliction.

It is the opinion of many reputable practitioners who have examined this patient, that he has incipient tuberculosis complicated by a chronic naso-pharyngeal catarrh. Fortunately, we are now no longer obliged to rely upon family history, so-called, nor upon those phenomena which go to make up the evidence of the so-called scrofulous diathesis, which is regarded by many as a constitutional taint generally present in the subjects of inherited tuberculosis. In the absence of bacilli tuberculosis in the expectorated matter we are not wholly warranted in concluding this patient has not in some other part of the body, or it may be in the pulmonary substance itself, some masses of tubercle.

He has attained fair size and enjoyed most of his life in a comfortable state of health, not to say robust health. The enlarged lymphatic glands in the neck, the enlarged tonsils without inflammatory action, and the pale infiltrations with exudations of lymph here and there upon the Schneiderian and pharyngeal mucous membranes, show most conclusively the presence of an excess of lymph in his system. The disturbed respiration, the feeble pulse, the sleeplessness, and, I may say, general neurasthenia, arouses the suspicion that this excess of lymph in the system has much to do with the debility and generally broken-down condition of his health.

It must be remembered that the lymph is derived chiefly from the multiplication of the leucocytes, and they are exuded through the walls of the blood tubes into the lymph channels. These channels are found everywhere in great abundance throughout the whole economy. Large numbers of lymph-spaces, as they are called, surround the arteries and the nerve-trunks of the body. Large numbers of lymph-tubes are found in the naso-pharyngeal membrane. The tonsils are lymph-glands, and they are enormously enlarged in this case, and yet in no manner inflamed; indeed, the whole naso-pharyngeal membrane, as well as the tonsils, presents an abnormal pallor. The matter expectorated contains broken epithelial cells, pus cells, and lymph corpuscles, but no tubercle bacilli.

Now he must have such local treatment as will dissolve and tend to clear away the accumulating exudation in the nose and pharynx; he must have something likewise which will exert a similar influence upon the lymph exuded lower down in the air-passages, that he may expectorate more freely and consequently suffer less distress when he coughs. He must likewise have something which tends to liquefy and dissolve the lymph in the lymph-channels and glands throughout the entire body. He acknowledges no periodicity in the course of his sufferings, and the pale relaxed tongue, with the night-sweats, constitute, therefore, the only ground for suspecting the presence of miasmatic infection.

The tonsils, you must remember, are composed of convolutions. They are fissured, and in the depths of these fissures large quantities of mucus are said to be secreted. This is the case, however, in abnormal conditions only; in the normal state the tonsil is an exceedingly small gland, which presents a series of convolutions in that part of the mucous membrane which lies between the anterior and the posterior glosso-palatine ligaments. In the present condition, however, these convolutions, each containing separate compartments of a glandular body identical in all respects with the cervical and other lymphatics, assumes an ovoidal form, with indentures into which a probe may be passed to a considerable depth—in this case quite an inch, that being about the thickness of the enlarged gland. In each of these apertures or sinuses are quantities of decaying lymph, and now and then a little cheesy matter which represents one form of degeneration of lymph.

Rolling a small portion of cotton-wool upon the end of a flexible probe, and dipping it into carbolic acid, these sinuses may be thoroughly wiped out, and freed from their irritating contents.

He is to have one-fiftieth grain of bichloride of mercury and two grains of the sulphate of quinine before each meal and at bedtime. He is to use as a snuff for the purpose of dissolving accumulated masses in the nose and pharynx a powder made as follows:

℞. Pulv. sodii boratis, ℥j.
Pulv. sodii chloridi, ℥j.

M. Sig.—To be used as a snuff in small quantities frequently during the day.

He is to have for use with the atomizer, for inhalation to assist in cleansing the nose and pharynx, the following mixture:

℞.	Sodii boratis,	℥ ij.
	Sodii chloridi,	℥ j.
	Acidi carbolici,	℥ ss.
	Aquæ destillatæ,	℥ xij.
	Aquæ camphoræ,	℥ iv.

M. Ft. solutio. Sig.—Use with the atomizer.

In addition to this, he is to have one of Blancard's pills of iodide of iron after each meal.

Now comes the most important part of the treatment, since the medicines have all been prescribed.

We are to devise some means by which the excess of lymph from which he is now suffering shall not be renewed. It has been found that an animal partaking of cooked fruits, molasses, jellies, in fact, glucose in any form whatever, experiences a rapid increase in the leucocytes in the blood, followed speedily by turgescence of all the lymph tubes in the body and engorgement of the lymphatic glands. Moreover, lactic acid fermentation takes place in the alimentary canal, the renal secretion is reduced in quantity, and is often found to contain large quantities of glucose.

Glucose seems to be in the nature of an artificially-digested food, which enters the system in great quantities through the absorbents in the alimentary tract.

Now, saccharose and starch, taken as food, cause an increased activity in the leucocytes, for both tend to increase the temperature of the body by promoting cell action, and in this way are force-producing agents. If the starch and the saccharose be artificially digested by heat before they are introduced into the system, they simply create an abnormal increase of what would otherwise be a normal action of all such agents, with the single exception that they are especially liable to disturb the alimentary canal in addition to lymphatic engorgement. We shall feed our patient abundantly on all kinds of meats and good vegetables plainly cooked; he shall have milk, butter, and cheese in abundance; he shall have all the ripe, raw, and seasonable fruits, fresh and in their natural state, and under this plan of treatment he shall rapidly recover; his enlarged tonsils shall disappear, and in six weeks from this time, if no accident happens, and I am not seriously mistaken in my judgment, which I assure you is based largely upon experience, this patient shall be regarded a sound man.

—Fear closes the ear of the mind.

COMMUNICATIONS.

INFANTILE ERYSIPELAS.

BY E. W. MITCHELL, M. D.,

Of Cincinnati, Ohio.

In a paper on the above subject, read before the Cincinnati Academy of Medicine, October 23, 1886, the author reported the following interesting case:

Annie ———, æt. eight months, in perfect health prior to her present attack, living in the country with the best possible surroundings as to hygiene. No other cases of erysipelas had existed in the neighborhood, and she had not been away from home for some time. No wound or abrasion was noticed. On July 19th she was feverish, and the mother noticed at the same time a spot of redness and swelling on the right labium pudendi. I was first called on the 22d. The characteristic eruption of erysipelas now covered the vulva and gluteal folds. Temperature 104°, pulse 160; child restless and sleepless. Ordered tr. aconit. gtt. two-thirds, every hour till fever should subside, when the dose was to be reduced to gtt. one-half; tr. ferri muriat. gtt. ii every two hours, well diluted; locally a lead wash. By the 24th, the fifth day of the disease, the eruption extended on both limbs to the knees, and on the back to the lumbar region. Evening temperature 106°, its highest point; pulse 160; slight cough. Fine mucous rales heard over the right lung. The local application was now changed to white lead paint well rubbed down with oil. By the 26th (seventh day) the eruption covered the back, extended below the knees, and was beginning to invade the abdomen. Temperature 103°–104°, pulse 160; cough had subsided, rales were no longer heard; dose of iron increased to gtt. iv every two hours.

During the next few days the eruption was slowly extending over abdomen, thorax, and lower limbs. After the thorax was covered, it then extended down the arms, next spread up the neck, appeared in front of the ears, spread over the face, and finally invaded the scalp. The whole surface of the body, by August 5th (seventeenth day), was covered. While spreading over new territory the eruption was fading out over those parts first affected, and several times there were fresh attacks, which were limited in extent. July 30th (eleventh day), respiration again became very rapid. She had a cough, and there were mucous rales in both lungs. This

attack subsided again in a day or two, but another more severe, with expulsion of mucus, appeared on the 10th of August. From this time there was very rapid breathing, cough and expectoration, during the rest of the sickness. These symptoms at times subsided, and again became severe. On August 5th she had a severe convulsion, followed by coma, lasting a short time. The convulsions recurred at intervals. A large abscess formed on the head, over the site of the posterior fontanelle, which was first aspirated, and upon refilling opened. The abscess was first noticed on the 31st day of the disease; it evidently added much to the suffering of the child, as well as being a drain upon her physical resources. On the 34th day I was told by the nurse that the child looked as if she had the measles. Examination disclosed a petechial eruption covering nearly the whole body. During the last few days the urine was very scant, but none could be collected for examination. Death September 15th, eight weeks after the beginning of the attack. There were never any symptoms of peritonitis or enteritis. The bowels were regular most of the time. The appetite was fairly good until the last week.

The principle of treatment kept in view was to nourish and sustain. Being upon the breast, her food was confined to the mother's milk. Regular hours of nursing were as much as possible observed. Iron and quinine, one or the other, were administered throughout. The aconite was discontinued after the first few days. The complication on the part of the lungs was treated by warm poultices over the chest, and small doses of muriate of ammonia internally. The convulsions were usually promptly controlled, and often when threatened, prevented by the hot bath. During the latter part of the disease wine or brandy was given in small doses. The lead paint seemed to delay the spread of the disease. On the face iodoform collodion was used. Although it seemed to mitigate the intensity of the inflammation, it did not prevent its extension. The doctor thought the unfavorable result in this case was to be attributed mainly to the complications.

SCHIRRHUS OF THE CARDIAC ORIFICE.*

BY E. BRUNO ZINKE, M. D.,

Of Cincinnati, Ohio.

German, æt. 46, family history good, fine physique, weight 220 pounds. He drank habitually 18 to 20 glasses of beer daily, yet was never seen intoxicated. He was a big eater, yet was never seriously ill. In September, 1886, he was taken ill with chills, fever, and sweating at irregular intervals, followed by jaundice, general malaise, loss of appetite, nausea, and morning vomiting, with irregular bowels. He had occasional tenderness and lancinating pain in the left side, under the ribs, which was readily influenced by turpentine liniment. Liver enlarged. He recovered under treatment at the end of two months and was discharged, the diagnosis being gastritis. He had also had a hemorrhage in the beginning of the attack. During the winter he had another attack of hematemesis; went to various physicians and the clinics, but gradually grew worse. The following April he presented himself to Dr. Zinke in the following condition: emaciated, hungry but unable to eat, cachectic, tongue coated, complained of a burning sensation from the middle of the œsophagus to the stomach, amounting to pain on deglutition. Solid food was rejected at once, and liquid was not long retained. There was excessive salivation (not mercurial), and digestion was accompanied by distressing hiccough and eructations. Left lobe of the liver very much enlarged. No tumor could be detected in the epigastric region. Temperature 100° F. Urine highly colored, and loaded with urates. May 13 he vomited a piece of hard cancerous substance, semicircular in shape, about an inch in length by half an inch in thickness, crumbling somewhat when rubbed between the fingers. After that he felt decidedly relieved, and was able to eat some. Though ordered a milk diet, he would at times eat meat and vegetables. He continued to improve; was able to be up and about the house until shorly before the last hemorrhage, after which he sank rapidly, and died ten days later of exhaustion.

For the relief of the digestive symptoms, one-drop doses of a one per cent. solution of nitro-glycerine were given with good effect three times daily. When this medicine was withdrawn for any length of time he immediately grew worse. Medicines to relieve the constipation or diarrhœa were the only other remedies given, with the exception of the last two weeks, when morphia was given to procure rest and sleep.

Post-mortem.—Large cancerous mass, involving the cardiac end of the stomach and lower part of the œsophagus, left half of the diaphragm posteriorly, posterior half of the base of the left lung, the spleen, tail of

* Read before the Cincinnati Academy of Medicine, October 18, 1886.

the pancreas, and the left flexure of the colon. The mucous membrane of the stomach presented the appearance of chronic gastritis. The cardiac orifice was so small that it with difficulty admitted the end of an ordinary probe. The calibre of the ascending and transverse colon was so small that they were taken for the small intestine.

Microscopic section of the cancerous growth showed it to be a soft scirrhus.

A remarkable feature, considering the size of the cardiac orifice, was the fact that the patient was able to swallow a large amount of food only two weeks before his death.

NOTES ON MEDICO-LEGAL TOPICS.

BY HENRY A. RILEY, ESQ.,

Of New York City.

ONE PHYSICIAN TRIES TO PREVENT ANOTHER FROM PRACTICING.

One of the daily papers recently had this account of a case where one physician tried to prevent another from practicing: Before Vice-Chancellor Van Fleet at Newark yesterday (November 1) a motion was made by counsel for Dr. Frederick B. Mandeville for an injunction to restrain Dr. George W. Harmon from engaging in the practice of medicine in Newark. The application alleged that in the early part of last year Dr. Mandeville entered into a contract with Dr. Harmon to act as his substitute during his absence for three months. The period was afterwards extended to October 1 of this year. Dr. Harmon continued to act until September 22, when he was released. The contract provided that Harmon should not engage in practice in Newark at any time after its expiration. The applicant claimed that this agreement was part of the consideration which led him to make the contract, and it was absolutely necessary for his protection, as the position Dr. Harmon took gave him opportunity to learn Dr. Mandeville's business, get acquainted with his patients, inspect his accounts, and learn his special and private formulæ and prescriptions, and also to learn professional secrets, which Dr. Mandeville had a right to keep from the world. In his answer, Dr. Harmon says that the real contract is contained in a letter from Dr. Mandeville to him, dated April 6, 1885, in which he is offered $500 a year for three months and a proportion of the excess of business during that period, and that no restraint was imposed on him. It was after he had been employed that the contract was drawn up. The Vice-Chancellor said he would take the case into consideration.

COLORED ECLECTICS.

The following account of a case before the Mayor's Court of Pittsburgh is curious, and shows that colored physicians in their practice are quite eclectic: At the hearing this afternoon (November 5, 1886,) before Acting Mayor Bell, of a case where a negro physician, Henry Thornton, was credited with the power of reviving waning affections between man and wife, it was developed that Thornton had informed the husband of Mrs. Virginia Emerson that if he would place a piece of his wife's clothing in a bottle and bury it, he could do what he pleased with her. The wife, on the witness stand, stated that although unaware of this proceeding it had the desired effect, as against her will she was compelled to crawl along the floor of her house. Then the bewitched bottle was brought to her and broken, when her instant recovery followed.

THE RULES OF THE PUBLIC SERVICE AND PROFESSIONAL ETHICS.

The rules of the public service sometimes seem to come in controversy with professional ethics: at least, Dr. Garnett, of Washington, D. C., finds fault with the regulations of the Pension Office. Commissioner Black recently sent Dr. Garnett this letter: "Your certificate of sickness in the case of Miss ——— is hereby returned to you, as it is not sufficiently explicit. The rules of this office require that physicians shall specify the trouble with which the patient is afflicted. I have therefore to request that you make a new certificate and forward to this office accompanied by this letter as soon as practicable. The certificates of physicians are treated in this office with the strictest confidence."

Dr. Garnett has refused to furnish the certificate demanded, and has written a letter to the Commissioner denying his right to ask for such a certificate. He says: "In all civilized countries the relation between the medical man and his patient is regarded as a private compact, involving the personal honor of the former and possessing all the sanctity implied by an oath—one which no honorable member of the fraternity could violate without entailing upon himself personal disgrace. * * No medical man in this city, who possesses a proper self-respect and correctly appreciates the dignity and responsibilities of his profession, will ever demean himself so far as to comply with such a rule. In the particular case referred to in your

note, I have already informed you that the party has been under and still is under surgical treatment which physically unfitted her for the performance of her official duties."

Commissioner Black has made a number of mistakes in the administration of the Pension Office, and this last edict seems to to be another. There is little doubt but that Dr. Garnett will get the best of the Commissioner, and force him to be content with the first certificate.

THE MENTAL CAPACITY OF A DEAF MUTE.

The New Jersey Court of Chancery has decided in a case of a deaf mute that she had no mental capacity sufficient to transact business, and could not select an agent to act for her. The person was deaf and dumb ever since she was two or three years old. Lord Hale held in England many years ago that a person deaf and dumb from birth was in presumption of law an idiot, but this presumption could, it seems, be rebutted by proof. At the present day the rule seems to be that there is no presumption at all, but that every case is to be decided by the proof presented of capacity or incapacity. In the case at issue the evidence was very strong that the woman was incompetent, yet the jury decided that she had power to choose an agent. It appeared that she was ignorant, having never been taught any language; that she could not comprehend any business transaction except perhaps the simplest, involving not more than a dollar; that she had learned to fetch and carry, do ordinary housework, and cook a meal; that she understood about such matters through motions; that she had never managed her own property, although about sixty-five years old, and knew nothing about its amount or mode of investment. An application was made to set aside the inquisition of the jury, and the court granted the application, as was clearly the sensible thing to do.

AN INTERMEDIATE PENITENTIARY.

While the Prison Association is meeting at Atlanta, and right in the section where the convict lease system is entrenched, is attacking it with vigor, it is noticeable that attempts are being made in other places to make the convict's lot a more hopeful one. The corner-stone has just been laid at Mansfield, Ohio, of a new Intermediate Penitentiary, with imposing ceremonies, in which ex-President Hayes, Governor Foraker, Senator Sherman, and others, took part. This Intermediate Penitentiary is an experiment for the reformation of convicts, and will be devoted to "first term" and "light sentence" criminals. The purpose of the law establishing the penitentiary is to keep those convicts of whose reformation there is hope separate from the older criminals.

INTERESTING BEQUESTS.

Samuel Johnson, a resident of Chicago, by his will, which has just been probated, makes some bequests which will be of interest to the profession. He bequeathes $10,000 for the erection of a bronze statue of Shakespeare in Lincoln Park, Chicago; $25,000 for the Chicago Nursery and Half-Orphans' Asylum; $50,000 for St. Luke's Hospital; $10,000 for the Cincinnati Orphan Asylum; $10,000 for a gateway at the main entrance of the college yard, Harvard University; and $500 to help preserve the Hamlin Burying Grounds, Middletown, Conn.

MISS WELTON'S BEQUEST.

Mr. Bergh is quite happy over a decision just rendered that the will of Miss Carrie Welton is a valid one. Miss Welton, it will be remembered, was frozen to death about a year since while traveling in the Rocky Mountains, and left a will which made a large bequest to the New York Society for the Prevention of Cruelty to Animals. The Society is now in a very prosperous condition, and is receiving frequent gifts and bequests.

The will of Col. Fuller, of the United States Army, has been contested on somewhat similar grounds to those in the Welton case, and it is a curious circumstance that Col. Fuller met his death quite near where Miss Welton was overcome by the cold. The Fuller case comes up in the Washington courts, and if the will is sustained, the Society will be the richer by about $60,000.

It is interesting to note in this connection that a Mr. Benjamin Moore, who recently died in Berlin, left a will giving a reward of one dollar to every policeman reporting a case of cruelty to animals. He said in his will: "As men have no hearts, I leave my money to the brutes;" and so it came about that the Berlin Society for the Protection of Animals became the possessors of about $100,000.

Medical Societies.

GYNÆCOLOGICAL AND OBSTETRICAL SOCIETY OF BALTIMORE.

(*Concluded from page* 654.)

Dr. Howard had operated in another case of the neurotic class. Miss B., aged 20, consulted him in April, 1884, and was under

care for nearly three months. For more than two years she had suffered from intense and almost incessant cephalalgia. She had no uterine disease, but was constantly in a hysterical and hyperæsthetical condition. She had been treated by a highly intelligent physician in Virginia without relief, and he had taken her to an eminent physician in the city of New York, who inserted a seton in the nape of neck and one in each iliac fossa, which only produced local suffering, but in no way alleviated the intense headache, which nothing but large hypodermics of morphine could diminish, and give some hours of disturbed sleep. She went home unimproved, but returned again, and on November 3, 1884, as she always complained of great pain upon pressure over the ovaries, both ovaries and tubes were removed. No unfavorable symptoms followed the operation, and the cephalalgia soon diminished. Her parents were delighted with the result, and she returned home January 14, 1885. She seemed a new being—a handsome girl, of noble figure, and the only child of her parents. But the fates were against her. Some months subsequently, she sustained injuries from an accidental fall, which terminated her life in a few days. Dr. Councilman, our eminent pathologist, made the following report: "The ovaries contain cysts of various sizes, due to simple dilatation of the Graafian follicles. In addition to the cysts, there is a good deal of induration of the stroma, and in the right ovary an enormous formation of blood vessels. In character this vascular formation consists of small arterioles which are in general tortuous, and traverse the tissue in every direction. In some places they are so numerous that they resemble very much the convoluted sweat glands of the skin. In the left ovary, I found several of the so-called menstruation fibromas, due to fibrous degeneration of the corpus luteum. The fallopian tubes were dilated, and the mucous membrane thickened and hypertrophied."

Lastly, Dr. Neale referred to a class of cases, which, under the lead of Mr. Lawson Tait, has excited great professional interest, and is, at present, the subject of warm dispute, viz., the removal of the uterine appendages for chronic intra-pelvic trouble of a painful and persistent character. In this country, under the lead of Dr. Thomas Addis Emmet, these cases are usually classed under the head of *pelvic cellulitis*. In Mr. Tait's view, these are *chronic ovaritis*, *chronic salpingitis* with occlusion of the tubes, which are distended by serum, pus, or blood. In many of these cases, Mr. Tait candidly admits that the diagnosis is uncertain. But when it can be made out with reasonable certainty—when suppuration has occurred in the ovaries, and the tubes are occluded and filled with pus—all now admit that the ovaries and tubes should be removed. What no one denies need not be discussed. But there are other cases which Mr. Tait would call *pyo-salpinx*, Dr. Emmet would call *cellulitis*—and many of them—that certainly do recover under judicious treatment, without removal of the uterine appendages. Call them what you like—*many of these cases get well.* And why should this not be so? Are the ovaries and tubes, of all the organs and tissues in the body, inveterately rebellious to remedies and methods of cure which effect cures in other organs and tissues? Is it at all probable that the All-wise Ruler of the Universe has endowed woman with organs that are essential to the propagation of the species, and yet made *them alone* incurable when inflamed, save only by an operation which defeats the object of their creation? It is a serious matter to sterilize a young woman forever, and, in Dr. Howard's judgment, it ought not to be done until all reasonable efforts to relieve her sufferings have failed. He held that in any case, whether of the neurotic class or that now under discussion, if an exploratory incision is made and the ovaries and tubes found healthy, they should not be removed. It is high time that a restraining hand should be laid upon those who are so eager to sterilize women.

Dr. L. E. Neale, with reference to Dr. Chunn's remarks explanatory of the non-appearance of the ascitic fluid after the operation, said he could not understand how a mere incision into the peritoneum could possibly produce such results. But he did understand how exposure, manipulation, sponging, and washing out the peritoneal sac could so alter its function. Indeed, this is a clinical fact, also applicable to other serous membranes, observed by Lawson Tait (*Dis. of the Ovaries*, ed. 1883, p. 253–4,) and others, and, as far as Dr. Neale knows, denied by none.

Dr. Neale credited Dr. Howard with making a correct diagnosis, if any *positive* diagnosis was made.

If Dr. Howard held that the ovaries should always be spared when they did not present microscopical evidences of disease, Dr. Neale must differ with him. The typical case of Olshausen quoted in the paper, and a number of similar observations by

others, might be cited to prove that success may attend the operation of castration when the ovaries are apparently normal. Can we tell by merely looking at the ovary whether it is diseased or not? Does Dr. Howard believe in functional disease, or more correctly in serious functional disturbance of an organ without gross anatomical alterations? Ovaries thought to be normal have been found by histological examination to be diseased, hence Battey has abandoned the term normal ovariotomy.

Dr. H. P. C. Wilson said there are exceptional cases, where the patient is afflicted with neurotic troubles, evidently reflected from the uterus and its appendages—greatly aggravated with each return of menstruation, and where every means of relief had been tried without any good result, in which he would not hesitate to remove the ovaries and tubes, although at the time of operation he could not discover disease in the parts. A superficial examination by sight and touch, such as we can obtain during the progress of an operation, is not sufficient to establish beyond doubt the existence of health or disease in these parts.

Be this as it may, we find a woman with all sorts of neurotic troubles—a misery to herself, a burden to her friends, incapacitated for any of life's duties—in agony of pain, referable to the pelvic organs, probably in convulsions about the menstrual period, and with all her symptoms aggravated at these times. She had gone the round of physicians, and exhausted all surgical and medical remedies, and yet nothing better.

He would not hesitate to remove this woman's uterine appendages, whether they *appeared* to him, on opening the abdomen, healthy or unhealthy—not simply to get rid of these parts, but by getting rid of them to remove the stimulus to morbid and excessive innervation and circulation in the uterus, and stop its reflected neurosis. As long as menstrual life continues, so long will these miserable women drag out a wretched existence, and we are called upon to arrest this function by removal of the ovaries and tubes.

He could recall one woman from whom Dr. Robert T. Wilson removed the uterine appendages, who was having from five to twenty hystero-epileptiform convulsions daily, and who, from these, and great pain, especially in the pelvis, was worn away to a skeleton, and bed-ridden. He and Dr. Robert T. Wilson had exhausted all their power by local and constitutional treatment, for her relief, but without any benefit. This woman is now leading an active life, and getting her living. When the abdomen was opened they could discover no disease in the ovaries and tubes by sight and touch.

Dr. B. B. Browne thought that in some cases in which the ovaries have been removed no examination of the tubes has been made. He thought that in every case the condition of the tubes should be determined, as it would have a very decided bearing upon the prognosis. He thought that if the ovaries were removed, the tubes were of no use, and should also be taken away.

Dr. W. T. Howard did not know whether in Dr. West's and Dr. Chunn's cases the tubes were removed or not; nor did it matter, as it was not pretended that either ovaries or tubes were diseased. Dr. Howard asked Dr. Browne if he knew of any physiologist who believed that the tubes caused menstruation? It was true that Mr. Lawson Tait had reported a case in which he had removed both tubes that were occlnded and distended with pus, left the ovaries, and eight months afterward the woman had not menstruated. And this seemed to sustain Mr. Tait's opinion that the ovaries have nothing whatever to do with menstruation, and this physiological function is dependent upon the fallopian tubes. But it is well known that women often have amenorrhœa for months and years who have both ovaries and tubes. And Mr. J. Knowsley Thornton has reported two cases which are a complete offset to Mr. Tait's one case. In both cases Mr. Thornton closely and thoroughly removed the tubes; but in one of the women about two-thirds of one ovary was left; and yet both women continued to menstruate regularly. Further, Sir Spencer Wells states that if the ovaries be not completely removed and some small portion left, menstruation may recur quite regularly, even though both tubes have been totally removed. No one denies that *diseased* tubes should be removed; but when they are healthy, their removal is unnecessary, since they, like the uterus, undergo atrophy when the ovaries are gone.

Dr. Neale and Dr. Wilson avow their readiness to extirpate the ovaries in women of the hystero-epileptic or neurotic class, whether, upon an examination by sight or touch during an operation, they can discover any disease there or not. And Dr. Neale asked whether Dr. Howard thought there can be serious functional disturbance of an organ without gross anatomical alterations; and affirmed that ovaries thought to be normal have been found by histological examination to be diseased, and that, therefore, Battey

has abandoned the term "normal ovariotomy." Dr. Howard certainly thought that there may be extremely painful and distressing symptoms in functional disorders of an organ, as in cases of irritable heart, entirely unconnected with any evidences of inflammation or structural lesions. And if in the heart, why not in the ovaries? Dr. Neale's reference to Battey was unfortunate; for Battey tells us that he has abandoned the absolute term "normal ovariotomy," because he removed ovaries in the early history of his operation that, in his ignorance of their histology and pathology, he erroneously supposed to be healthy, that he now finds were really diseased. It may be true that there may exist morbid alteration in the ovaries that can only be discovered by the microscope; still, of what avail is that before and during oöphorectomy? But if such information were available, does it follow that such minute alterations of necessity demand removal of the ovaries? It is well known that in ovariotomy operations, ovaries that were obviously somewhat diseased both to the sight and touch had been left, and the women have subsequently borne children.

But if Dr. Howard was wrong in his opposition to the removal of healthy ovaries in cases belonging to the neurotic class, it must be conceded that he is in excellent company. In the September number of the *American Journal of Obstetrics and Diseases of Women*, Mr. Lawson Tait affirms that "save when the seat of such *organic disease* as will *explain genuine suffering*, the uterine appendages ought *not to be removed;*" and in the same number of the same journal he declares that "the ovaries should never be removed unless they are unquestionably diseased, that is, unless an *anatomical alteration can be detected without doubt by a physical examination.*" And Battey stated at the meeting of the American Gynæcological Society in this city on the 21st September, just passed, that not even "every case of *organic disease* of the ovary should be removed." All know that these gentlemen are the highest authorities on the subject.

NEW YORK NEUROLOGICAL SOCIETY.

Stated meeting, November 2, 1886. The President, C. L. Dana, M. D., in the chair.

A Case of Bitemporal Hemianopsia.

Dr. Edward Waitzfelder presented the patient, a lad whose general history was negative until five months ago. He then noticed a "blur" over the right eye. He consulted Dr. P. A. Callan at the New York Eye and Ear Dispensary, who diagnosticated right temporal hemianopsia. The condition grew worse; the left optic nerve became involved, and left temporal hemianopsia devolved. The nasal fields of both eyes were unaffected. Two months ago the patient had choked disk in the right eye. His condition, November 1, was as follows: No other basal nerve affected; he has complete bitemporal hemianopsia, the whole of fixation point being included in the seeing field. Theoretically, the fixation should be bisected; but practically it never is. There is atrophy of both optic nerves, most marked in the right. Vision, R. E. 8-200; L. E. 20-20.

Diagnosis.—Tumor of the chiasm in the anterior portion; pressure upon the fasciculi cruciati of both optic nerves, the fasciculi laterali being as yet unaffected. There is no tubercular or syphilitic history. The rapid growth of the lesion points strongly in the direction of sarcoma.

So far as Dr. Waitzfelder could ascertain this was the first recorded case in the English language. The point of special interest in the case was that the fixation point was "dodged" by the line of the hemianopsia. Why this was so he could not say, but it would seem to indicate that there was a special set of nerves intended only for extreme central vision.

Remarks were made on the case by Drs. Pooley, Webster, Starr, Leszinsky, and Bullard.

Thomson's Disease.

Dr. George W. Jacoby presented a young man suffering from Thomson's disease. The history will be published hereafter.

Remarks on Cocaine and the So-called Cocaine Habit.

Dr. W. A. Hammond made some remarks upon his personal experience with some of the preparations of cocaine. He had used only the fluid extract, various wines, and hydrochlorate of cocaine. The fluid extract had been discarded by him since two or three years, mainly because it had been badly borne by the stomach. It excited nausea, and was disagreeable to the taste. He then began the use of the wines; but finding that they differed so much in their effects, he gave them up until he suggested to Thurber & Co. to try to make a wine of coca free from tannin and extractive matters, and they had, he believed, entirely succeeded in doing so. There were two grains of the hydrochlorate of cocaine to the pint of wine. With this

preparation he had had an extensive experience, not only upon others, but upon himself. He had used it in spinal irritation with excellent results—results which could not be attributed alone to the wine, but in part to the cocaine. He had used it also as a general tonic and for fatigue. For some time past he had been in the habit of taking a wineglassful at the close of his day's duties, and with benefit. It certainly had a decidedly restorative effect without being followed by a feeling of depression. He also had used it in some cases of dyspepsia with a very irritable state of the stomach. He supposed its action was by lessening the sensibility of the stomach, as it lessened sensibility when applied to other parts. It was remarkable to what an extent the irritability of the stomach was overcome by doses of two or three teaspoonfuls of the wine of coca, repeated at intervals of fifteen or twenty minutes until half a dozen doses had been taken. If the first doses were vomited, the succeeding ones would be retained longer, until finally they were retained altogether. Cases of irritability of the stomach due apparently to spinal irritation had been relieved within a few hours by this treatment. Generally when he wished in any case to produce a powerful therapeutical effect, he employed the salt. Dr. Hammond here spoke briefly of the physiological effects of coca, and said that the first writer, Tschudi (?), who had described its effects upon the native Indians of South America, gave an exaggerated account of its baneful influence, and his ideas had been copied over and over again, without the authority being given, until our minds had become thoroughly indoctrinated by them. That author said, among other things, that the coca rendered the teeth black, produced ulceration of the tongue, caused the breath to become fetid, the jaws to become ulcerated, the bones to soften, and rendered the patient an idiot. But subsequent observers said that such results must be entirely exceptional, as they had never seen them. If there was discoloration of the teeth, Dr. Hammond thought it might be accounted for by the lime which the Indians mixed with the leaves, or by the presence of tannin. There had recently been some very striking stories in the newspapers regarding the injurious effects of the drug upon persons who had become addicted to its use. In order to determine whether there was any truth in these statements, Dr. Hammond made some experiments upon himself. He first injected hypodermically one grain of the hydrochlorate of cocaine, which caused an exhilaration of spirits and a happier state of mind than he had enjoyed during that day. He was unable to sleep that night until four or five o'clock in the morning, and when he got up he had a severe headache. He also had a large evacuation of urine. The effect of the drug was to produce an exhilaration, such as would be produced by two or three glasses of champagne. The next night he injected two grains, which produced the same pleasant feeling, and in addition he felt an inordinate desire to write. He wrote eight or ten pages of foolscap, and thought it was the best that he had ever written, but the next morning he found that it was the most extreme nonsense. Each sentence was complete in itself, but no two sentences had any relation to each other. The first part was more incoherent than the latter. The next night he injected three grains, and although he again felt the disposition to write he did not indulge it, but he talked a great deal and made speeches. He knew what he was about, and was able to restrain himself, but it was pleasant to speak. He went to sleep late, and again awoke with a severe headache. It was a peculiar fact in his case that at the point of injection there always developed redness, swelling, stopping short only of an abscess. He now had several hard spots on his arm, and waited four or five days, when he injected six grains of hydrochlorate of cocaine, three grains at two different places. He then felt decidedly "upset," yet he did not lose consciousness nor his relation to things. He gave instructions to the servants correctly. But he did not feel a strong disposition to write or to talk. He was unable to sleep at all that night. The injections were always followed by large evacuations of urine, and by headache next day, but without debility. Three nights later he injected eight grains, with about the same effects. The next night he injected eighteen grains, making six different punctures, all inside of twenty minutes. He became intensely exhilarated, and was unable some hours afterwards to recall what he did. He was in his office, but in some way got to bed, and the next day he found things in more or less disorder in his office. His headache remained for two days, and there was great action of the heart, palpitation; he could hear it beating on raising the arm to the head. Exaggerated action of the heart had also attended the smaller doses. But he experienced none of the horrible effects which were said to attend the use of the drug in large or continued doses, no disposition to murder or commit acts of violence.

He acquired no habit. He was able to quit its use at once, and regarding the cocaine habit he would say that he had given the drug in doses of from one to five grains for three months to a lady suffering from exophthalmic goitre, and she was then able to discontinue its use without any difficulty. At no time did she manifest any loss of moral principle. She took two doses a day. From a theoretical standpoint, perhaps cocaine should not be administered in this disease, but it proved beneficial in this case, for the heart's action, which had been increased, diminished, became steadier, and the patient felt much better. He also gave it for some months to a lady addicted to the opium habit, carrying the dose up to five grains injected once a day. It overcame the opium habit, and the patient failed to acquire the so-called cocaine habit. In this and other patients to whom he had administered cocaine, it produced, as in his own case, extraordinary action of the heart, increased temperature, and blood-pressure, perspiration, and indisposition to sleep.

He had used a ten per cent. solution of cocaine, soaked in lint and applied to the vulva, for the relief of masturbation, but it had failed in one case, that of a girl four or five years of age. It had been ineffectual in boys, applied to the glans penis.

In three cases of melancholia in women who refused to speak, injections of hydrate of cocaine had overcome the prolonged silence. The first was a marked case of melancholia with stupor, and the patient had not spoken for nine months. At the first sitting he injected one grain of hydrate of cocaine. The patient then nodded or shook her head in reply to questions, but would not speak. At the next sitting three grains of the drug were injected, and within four minutes the patient replied to questions by yes and no, and within ten minutes she began to talk, and kept on talking, although incoherently. She did not sleep that night, and seemed to have pain in the head the next morning. The next injection of three grains caused the patient to talk, but less incoherently. This was a year ago, and the patient continued as melancholic as before, bnt she talked, if that was any advantage. Dr. Hammond had failed occasionally to induce patients to speak by injections of cocaine.

As to the cocaine habit, Dr. Hammond regarded it as similar to the tea or coffee habit, and unlike the opium habit. He did not believe there was a single instance of well-pronounced cocaine habit, the patient being unable to stop it at any time if he chose to do so. If a person were to continue its use for a long time, he should be inclined to look for trouble with the heart rather than with other organs.

Dr. J. B. Mattison, of Brooklyn, could not agree wiih Dr. Hammond that there was not a cocaine habit. Within a few months, Dr. Mattison has had seven cases of the cocaine habit under his care, five in physicians, two in druggists. He certainly believed there was such a thing as cocaine addiction. He regarded the drug as most dangerous and destructive of the tissues. In certain cases its action was more unfavorable even than morphine. The cases reported in the newspapers he thought were founded on facts. In one instance he wrote to a physician asking whether the report was true that a certain doctor had been arrested in the street under the influence of cocaine. The physician replied that it was true; that the doctor was a victim to cocaine. He could cite other similar cases. In one instance a physician attempted to write a prescription for a patient, but instead wrote for the sheriff to come and take him to jail.

The effects of cocaine, as far as he had observed, were similar to those described by Dr. Hammond, but besides the action upon the heart, the great volubility and the unrest he had noticed hallucinations and delusions, but no homicidal or suicidal tendency. In some cases there was marked emaciation. He thought the effects of the continued use of cocaine were more decided than those of the continued use of morphine. The patients whom he had treated had acquired the cocaine habit gradually, making comparatively small injections several times a day. Dt. Hammond seemed to think that no dose was toxic, but Dr. Mattison regarded Dr. Hammond's case as exceptional, and he would not advise any physician to repeat the experiment.

Dr. J. Leonard Corning thought there was a morbid fear of cocaine spreading throughout the community, and he thought the remarks of Dr. Hammond were timely, as they would tend to allay the prejudice against a most useful remedy.

Dr. L. C. Gray remarked that between Dr. Hammond on one side and Dr. Mattison on the other there was considerable distance, and he did not know how the question could be solved except by further experience. Dr. Hammond's statement that no cases had been reported by medical men was a mistake. Cases had been reported in Europe; but they were not numerous.

Dr. M. R. Richard said that about six years ago he had a case of despondency in a lady disappointed in love. This was in New Orleans, and a physician there told him that he was in the habit of using an infusion of coca leaves in such cases. He gave it to this woman with happy results. Three years ago he came to New York and was unable to find any coca leaves. Taken in this manner the patient would not be likely to get a sufficient amount of the drug to acquire a habit.

The President read a communication from Dr. C. H. Hughes, of St. Louis, in which he said: Most of the cases of cocaine habit seen by me have been mixed cases of opium, cocaine, and alcohol or ether inebriety, combined, or alternating; though, I think, I know of cases where cocaine is the chief, if not the exclusive, reliance. But these patients are not reliable in their statements. I have not seen a physician addicted to cocaine who stuck to cocaine exclusively. The finale has generally been cocaine, and opium, and whisky, and ether, and all the other neurotic stimulants. Opium is a much more agreeable stimulant, and most patients evidently try to get back to the fatal bliss of opium. I have never relied on cocaine alone in breaking up the opium habit. I never use cocaine to intoxication, and never regularly. My rule with cocaine cases, as I usually see them, is to get them back to plain opium, and then break them of that if advisable.

Dr. Hughes referred to the fact that in some cases cocaine produced poisonous effects.

The President referred to thirteen cases of cocaine habit reported by Erlenmeyer, and to a case reported by Bornemann. The subject, he said, had recently been discussed at the meeting of the German Congress of Physicians and Naturalists, when Dr. Smidt reported some cases of cocaine-morphine habit. The general opinion was that pure cocaine addiction was rare, but that the cocaine-morphine habit was not so, and was a very destructive and pernicious habit.

Dr. Hammond, in closing the discussion, said he did not deny the existence of a cocaine habit; he only claimed that it was unlike the opium habit, for the patient could break it off at will. He was aware that patients addicted to the use of opium sometimes added cocaine, greatly to their detriment. As to cocaine being a poison, twenty, and even thirty-two grains had been taken without serious results. He differed from Dr. Mattison, who thought it was more injurious employed hypodermically. But the patient came under its influence more slowly when it was taken into the stomach.

The President reported for Dr. Herman M. Biggs a

Case of Subacute Spinal Paralysis,

and exhibited specimens of the cord and sciatic nerve. The case was one characterized by gradual paralysis of the lower, and then of the upper extremities, moderate atrophy, later a slight anæsthesia of the lower extremities; no pain, loss of tendon reflexes, and no bladder troubles. The course was progressive. Death took place in five months.

Autopsy.—The patient was a male, aged fifty-two, not syphilitic. The interest in the case lay in the rarity of the affection, and especially of cases in which post-mortem observations had been made. Clinically, it resembled mostly the subacute spinal paralysis of Duchenne, although that disease is very rarely fatal. It still more strongly resembled a chronic form of Landry's acute ascending paralysis, and gave support to Ross's classification of

1. Landry's paralysis.
2. The subacute paralysis of Duchenne.
3. Periependymal myelitis.
4. Progressive muscular atrophy, as inflammatory processes attacking the central gray matter of the cord, and distinguished by the greater or less acuteness of the process.

The case was interesting also as showing that these paralyses are not always at least due to neuritis. Dr. Dana showed sections of the lumbar and upper dorsal cord, which he thought showed evidences of a low grade of central myelitis. The anterior roots and the sciatic nerve were apparently normal.

NEW YORK ACADEMY OF MEDICINE.

Regular meeting, October 28, 1886. Dr. Alexander S. Hunter, Chairman.

Section in Obstetrics and Diseases of Women and Children.

Maternal Nursing—Importance to the Child—Importance to the Mother—Its Influence in Preventing Diseases of the Pelvic Viscera—Also Wet-Nursing—Its Influence in Increasing Infant Mortality.

Dr. Joseph E. Winters read the paper. He believed that maternal nursing hastened involution and rendered it much more complete. He cited numerous cases to show that the return to the normal condition of the

pelvic viscera was usually delayed and often imperfectly accomplished when the mother failed to nurse her own child; that in this way the foundation for chronic disease was often laid.

Dr. Simon Baruch thought the principal good accomplished by nursing the child in producing involution took place during the first few days.

Dr. Partridge thought three months elapsed before the normal condition was established.

Dr. J. Lewis Smith and others also took part in the discussion, most of whom agreed essentially with Dr. Winters.

Dr. Winters, in the second part of his paper, strongly opposed the employment of wet-nurses, except when absolutely necessary. They usually belonged to the unmarried class; were often capricious and tyrannical, and infantile mortality was certainly increased by their employment, as they were apt to sacrifice either their own infant or that of their mistress, and their milk was of uncertain quality.

On Vicarious Bleeding from the Under Lip, with Cases, and Remarks on the Modern Treatment of Hemorrhoids.

Dr. Alexander Harkin thus writes in the *Lancet*, October 30:

Case 1. Mrs. M., aged 38 years, of bilious temperament, sallow complexion, dark hair and eyes, the mother of six children, called on me early in March, 1885. Before her marriage she had suffered from hemorrhoids, and during her first and subsequent pregnancies from hepatic congestion and occasional hemorrhage from the bowels, which frequently gave me some anxiety on her account. Among other troubles, in 1880 she was prostrated with profuse hemorrhage from a cluster of varicose veins connected with the left femoral vein and close to the knee-joint. On this occasion she presented every sign of debility and anæmia: blanched cheeks and lips, sunken features, compressible and feeble pulse, undue palpitation of the heart on the slightest exertion, continuous headache, and frequent vertigo. She attributed her exhaustion to a profuse bleeding from the under lip, occurring at every meal, and generally for ten minutes each time. On examination I found a slight abrasion at the junction of the epidermis with the lining membrane of the lip, about half the size of a threepenny coin, from which the blood flowed freely. Mrs. M. had removed from my neighborhood two years previously, and, as the hemorrhage from the piles had again become troublesome, acting on the advice of a physician of experience, she entered the Royal Hospital, Belfast, in February, 1883, where soon after the offending growths were deligated by one of the attending surgeons to that institution. After her return home in April, she experienced complete relief for a short time only, irritation about the anus occurring occasionally, and now and then a slight discharge of blood from the nostrils; but in the following June her left lip became painful, and blood began to ooze from it once or twice in the week; the intervals then became gradually shorter, the drain occurring every day, and for many weeks before her visit to me the discharge reappeared at every meal, or when accidentally the lip was hurt. Having from previous lengthened experience acquired a thorough knowledge of the patient's constitution and requirements, I did not hesitate in adopting a plan of treatment. I ordered the immediate application of a blister, eight inches by four inches, for eight hours over the region of the liver, to be followed by cotton-wool dressing. On visiting Mrs. M—— next day, I was informed that from the moment free vesication was established all labial hemorrhage had ceased, and a return of health begun to be felt. I then prescribed the use of chlorate of potash and iron in liberal doses; her color and bodily strength soon reappeared, her headache and vertigo troubled her no more, and, with the exception of an occasional feeling of pain at the seat of discharge in the lower lip, she has not had a recurrence of any of her former ailments. In January last she gave birth to a male child without any unusual trouble, and up to the present date (a period of two years and seven months) there has not been even the slightest sign of the hemorrhage.

Case 2. Mrs. McD——, aged thirty-six years, mother of six children, sent for me on March 8, 1886. I found her confined to

bed, pallid and exhausted from a profuse discharge of blood from the rectum, which had continued for several days, having delayed from motives of delicacy to send for medical advice; the blood accompanied every evacuation, and frequently after feeling a desire the motion consisted of blood alone, often to the amount of three or four ounces. On examination, I found a fringe of external piles surrounding the aperture of the rectum, and inside the sphincter a number of knotty tubercles, from one of which red arterial blood flowed freely. In this, as in the former case, I immediately applied a blister over the region of the liver, and ordered as an adjuvant a mixture of tincture of perchloride of iron and chlorate of potash solution. The relief was immediate, and the patient very soon recovered her natural color and strength, and was able to take out-door exercise. At the end of a fortnight, however, I was again called to the case, and found that the bleeding had returned as freely as ever, with great mental and bodily depression. The relapse was due to the patient having unwisely stood behind a counter to assist her husband for ten hours on a previous day. As her friends had now become anxious on her behalf, I requested Dr. Walton Browne to see the patient with me. After recognizing the nature of the ailment, we agreed to continue the hæmostatic medicine, and gave her a sedative at intervals. These remedies only gave her partial relief, and as the drain was still continuous and severe, at the request of the patient I reapplied the blister to the same place on March 28th. The remedy was again successful; all bleeding ceased, and has not made any reappearance up to the present date.

As bearing upon the etiology of these discharges, I wish to append the history of three recent cases in growing youths, very similar in character and cure.

On May 13, 1885, I was asked to visit J. B., a counter-hand in a spirit store. He had been subject to free bleeding from the right nostril at short intervals for many weeks; he also suffered from severe headaches and constipated bowels; no history of piles. On examining the region of the liver, I found the organ tender on pressure and somewhat enlarged. I then applied the liquor epispasticus freely over the hepatic region, telling the young man that after five hours the hemorrhage would permanently cease. I ordered some cholagogue medicine, at the same time giving him general directions as to diet. As I predicted, the hemorrhage ceased, and now after the interval of more than a year it has not returned.

On the same day (May 13th), a young man, apprenticed to a chemist, was brought to me by his father, who stated that his son had suffered very much from indigestion and vertigo, and that he had been bleeding from the right nostril for many days. I had formerly treated his father for congestion of the liver due to excessive drinking. On looking at the abdominal region, I found an enlarged liver, with congested cutaneous veins traversing the abdominal surface over that organ. I applied the fluid blister, with the usual result—an immediate cessation of the epistaxis. The young man has since emigrated, but until the day of his departure, six months after, the cure had been complete.

On May 25, 1885, J. S——, an in-door servant, suffering from profuse epistaxis from the left nostril, sought my advice. The bleeding had continued for six weeks, at intervals; it had first appeared at 6 a. m. and 9 a. m. daily, but latterly it observed no limits, coming on six or seven times in the twenty-four hours. On examination, I found a large and torpid liver; the patient had, besides, many of the subjective signs of the disease —disturbed sleep, headache, irritable temper, borborygmi, hardened fæces, high-colored urine, depressed spirits, inability to rise in the morning, and drowsiness during the day. I applied the counter-irritant over the site of the disease, and with the result that the epistaxis yielded at once as well as the other objective and subjective symptoms of hepatic disorder. After an interval of more than a year he has continued well.

It is freely acknowledged by all writers on the pathology of hemorrhoids that these adventitious bodies owe their existence chiefly to the congestion of a distant organ—the liver—or to obstruction, from various causes, of the great portal vein, through which the venous blood from the abdominal viscera passes into the liver. Van Buren* has called attention to the fact "that these veins, including the hemorrhoidal, are unprovided with valves, and that consequently, whenever the abdominal circulation is sluggish or obstructed, as by an overloaded colon, abdominal tumor, or congested liver, there is a strong tendency to stagnation in its lowermost tributary—the hemorrhoidal vein. When a mass of dilated veins is thus frequently subjected to bruising in the act of defecation, it is liable to an attack of inflammation, the connecting tissue surrounding the veins be-

*Diseases of the Rectum, p. 18.

comes infiltrated with exudation, and the morbid anatomy of the hemorrhoidal tumor is thus explained." With such a history of the genesis of piles, does it not appear strange that to a great extent the remedy is sought for, not in the removal or mitigation of their primary cause, but in their mechanical obliteration by ligature, by the actual cautery, or by the clamp? Yet such, unhappily, is too often the case; and what but serious injury must be the result, when this line of treatment is adopted in men with enlarged and indurated livers, with persistent engorgement of the portal system, and the circulation through the abdominal viscera almost completely obstructed? The fault, if such there be, is chargeable to the medical adviser, who, instead of proceeding upon physiological grounds and laboring to cure the disease by removing its cause, too often turns over his patients to the operating surgeon, and considers his responsibility at an end, when these erectile tumors, whether internal or external to the sphincters, are deligated in a scientific manner.

My first case clearly exemplifies the failure of merely surgical appliances in the absence of constitutional treatment, and the mistake of regarding a prominent symptom as the primary factor in the cycle of morbid phenomena. The violent suppression of a salutary discharge was soon followed by its re-establishment at the superior outlet of the digestive tract; and had similar methods been applied to its extinction on the labial outlet, we should doubtless have found that the nasal organ would in due course have protested, according to its wont, by profuse epistaxis, against the mere mechanical treatment of a systemic lesion. Would the doctrine of deligation be permissible in the latter case? The second example illustrates the advantage of counter-irritant and derivative treatment in immediately controlling and finally suppressing the hemorrhoidal flux, and in this manner superseding the necessity for operative procedure, with its attendant dangers and discomforts.

The frequent occurrence of epistaxis in youth is evidently due to the excitement and hyperæmic condition of the liver and digestive organs during the period of active growth and the constant demands on its functional activity. The liver at this stage closely approximates to the condition in after life, which is the causal factor in the development of piles, and as such is equally amenable to treatment in accordance with etiological principles; the derivative that cures the hemorrhoidal flux as certainly puts an end to the epistaxis, the outcome of hepatic congestion. The cases related are but the types of many others in a lengthened experience. I have chosen them as being of recent occurrence, and as sufficiently removed from the date of treatment to test the validity and permanence of their cure.

My object in this paper is to enter my protest against the unsound principles upon which hemorrhoids are so frequently treated, and the routine procedure adopted in the sudden suppression of a habitual discharge without sufficient attention to its remote cause.

Suicidal Penetrating Wound of the Neck; Recovery; Remarks.

Wounds of the front of the neck are the commonest of those met with in this region, and attended with so many dangers that it would take too much space to even enumerate them. In the following case, which Mr. Peck reports in the *Lancet*, October 30, the treatment adopted was most successful, the application of a stout silk ligature on each side being sufficient to keep in apposition the parts divided until firm union had taken place; this was no doubt much aided by the operation of laryngotomy. All danger of suffocation from the extension of local complication was thus prevented, and the patient enabled to breathe pure air. The introduction of a catheter into the œsophagus saved much difficulty in feeding the patient, more nutriment being introduced in this way than could otherwise have been given without great pain and considerable disturbance of the parts. In the majority of wounds of the anterior part of the neck it is not advisable to introduce sutures so as to close the wound; but in a case such as the one which we record, where a certain amount of antiseptic treatment can be applied and the smallest amount of disturbance of the parts is permitted, the introduction of sutures hastens the healing, and is certainly to be advised.

J. T., aged forty, a night-porter, had been a heavy drinker of beer for many years. There was gout on the father's side of the family, but no history of insanity. Latterly he had been much depressed, owing to having lost the securities for some money lent to a friend. He was found in a water-closet with his throat cut, lying in a pool of blood.

On admission, there was a wound four inches long, which commenced on the left side of the neck over the carotid sheath, and, passing across to the right side through the

thyro-hyoid membrane, terminated close to the right carotid vessels. The incision passed through the epiglottis, the larger part of which was left attached to the base of the tongue, and, having completely divided the middle constrictor of the pharynx, had laid bare at one spot the vertebral column, so that the upper part of the pharynx was severed from the lower, and the larynx and trachea had receded towards the chest for fully an inch and a half. There was no hemorrhage except some slight venous oozing. The house-surgeon, Mr. Page, brought together the divided edges of the middle constrictor with fine catgut sutures, having first passed a gum catheter through the mouth into the œsophagus. On temporary closure of the skin wound, intense dyspnœa came on, so as to endanger the man's life. A stout silk ligature was now passed on each side through the upper border of the thyroid cartilage below, and the tissues surrounding the hyoid bone above, and then by gradually drawing them tight the larynx was raised to its proper position. The ends of the ligatures were left long, and were brought out at the corners of the skin wound. Laryngotomy was performed, and a silver tube introduced. The skin wound was united with silver sutures and dressed with carbolized gauze. The patient was placed in a tent, the air of which was kept moist by a eucalyptus steam spray. The man was fed every four hours through the catheter. He passed a quiet night, but was a little restless next day. Owing to his attempting to bite through the catheter, it was thought advisable to remove it, and introduce one through the nose; this was more comfortable, and for twelve days he was fed entirely through the nose. On the twelfth day the stout silk ligatures came away, and sufficient union had taken place to retain the larynx in its normal position. The power of deglutition returned, and the nasal tube was removed. Afterwards there was no trouble in swallowing. In a few more days the tracheotomy tube was removed, the original wound having nearly healed, the tent and spray were dispensed with, and the man was allowed to get up. For several days rapid improvement followed, but on the tenth day after the removal of the tracheotomy tube there was difficulty in breathing, which culminated in an attack of spasmodic dyspnœa. Fortunately this was not fatal, but it was deemed necessary to reintroduce the tube through the crico-thyroid space. After wearing this for a week he was able to leave it off for several hours at a time, being trained to this by closure of the tube with a cork, respiration taking place through an aperture in the upper convex surface of the tube. On June 26th he was made an out-patient, wearing a silver tube, and came up daily to be watched while it was removed. At the end of August he left the hospital, being able to breathe freely in the normal way. The only change noticeable was a slight huskiness in the voice.

The Venom of Poisonous Snakes.

The investigation of the poison which in the form of snake-bites kills nearly 50,000 human beings per annum in India alone, cannot fail to present many points of interest, and has just been undertaken by Dr. R. Norris Wolfenden, whose results are published in the last part of the *Journal of Physiology*. The poisons with which he experimented were obtained from the Indian cobra, the scientific name of which is Naja tripudians, and the Indian viper, named the Daboia Russellii. In the report of the last Snake Commission, Dr. Wolfenden tells us, Mr. Pedler, one of the commissioners, sums up the results of his chemical examination into the nature of the poison, with the remark that it is quite impossible to draw any deductions as to its nature, and he thought it was more than possible that the poison was a mixture of albuminous principles with some specific poison. Sir Joseph Fayrer and Dr. Lauder Brunton compared the action of cobra poison to the alkaloid conia. Blyth thought that the poison could be separated from the proteids in the venom, and that it was not thrown down with the albumens on on the addition of alcohol. Walls, however, with whom Dr. Wolfenden agrees, ascertained that this is an error, and attributable to the circumstance that the alcohol used was not sufficiently pure. If to a solution of cobra poison absolute alcohol be added, a white precipitate is thrown down. After the precipitate has been thoroughly washed with alcohol, it can be redissolved in water, and the solution produces all the effects of cobra poison. Moreover, if dried cobra poison in a state of fine powder be added to absolute alcohol, and the mixture be frequently agitated, the alcohol will derive no poisonous property from the cobra venom; but if rectified spirit be employed, the water in the rectified spirit is capable of taking up a certain amount of the poison. This is just what might be expected of an albuminous fluid, and tells in favor of the view that the cobra venom is of a proteid nature. The observations and experiments of Weir

Mitchell and Reichert upon the venoms of several American snakes tend to prove that the poisonous principle is resident in the proteid constituents. Dr. Wolfenden finds the venom is generally acid when quite fresh, but that it may become neutral when it has been kept for a few hours. Experiment showed that the dialysates of the venom, free from proteid, were quite harmless; but that if they contained any proteid they became toxic. The activity of the venom, though reduced, is not entirely abolished by the exposure to a boiling temperature. It is rendered innocuous by the permanganate of potash outside the body, as well as by tannic acid, metallic salts, and other agents which precipitate albumen. The albumens which Dr. Wolfenden finds are present in the venom of the cobra are: First, a globulin, which is always present, and probably kills by interference with the respiratory mechanism—that is, by asphyxia, and without paralysis, causing local inflammation, but not of great intensity. Secondly, an albumen resembling acid albumen, which is precipitated, together with globulin, by saturation, and which is in some degree dialysable; this proteid probably acts on the respiratory apparatus chiefly like the globulin, but less intensely. Thirdly, an albumen which is precipitated by sodium sulphate out of the magnesia filtrate, and appears to be serum-albumen; this is also toxic, and produces a kind of ascending paralysis, with fatal termination by suppression of the respiratory function due to paralysis of the respiratory muscles. Lastly, he found some traces of hemi-albumose and of peptone. Similar compounds were found in the venom of daboia.

A Case of Removal of the Scapula for Osteo-Sarcoma.

Mr. Charters Symonds read notes of this case before the Clinical Society of London (Oct. 22). The patient was a man, aged 34, who remained well, and was shown at the meeting, two years having elapsed since the operation. Six months before admission, he fell and bruised his shoulder, attending for a month the Croydon Hospital, where he was told he had ruptured a muscle. One month after the accident a swelling appeared, and from that time advanced steadily, though without pain. The inconvenience was due entirely to its size, the man being unable to do heavy work. When admitted, he was healthy in other respects. To the dorsum of the scapula was attached a tumor, measuring nine to ten inches across, and projecting five inches from the surface. It moved with the scapula, and did not quite reach the glenoid cavity. The spine of the scapula could just be traced. On April 1, 1884, the whole bone was removed, except the acromion and coracoid processes. The usual transverse and vertical incisions were made, one flap only being reflected at a time. First, the inner flap was dissected off, and the posterior border of the bone freed. Next, the inferior angle was isolated, and then the anterior flap was reflected and the axillary border freed, the various muscles being divided. The deltoid and trapezius muscles were divided close to the spine of the scapula, and the superior border was freed. The growth was found to extend to the glenoid cavity; so, after sawing off the acromion and coracoid processes, the capsule of the shoulder-joint and the muscles covering it were severed. The whole mass was then raised from the chest, and the serratus magnus divided. The subclavian was compressed during the operation, and all the large vessels were seized with two pairs of forceps before being divided. In this way little blood was lost. The same evening the man had an unexplained attack of dyspnœa, which lasted twenty-four hours, and interfered with sleep. The temperature rose quickly, reaching its highest point 103.6°, on the fourth day, but instead of falling it passed into a hectic fever, which lasted till May 9th, and then suddenly ceased on the removal of the cause of suppuration—namely, the head of the humerus. Rapid recovery ensued.

Another clinical feature of interest was œdema of the arm without redness, and with no special fever. This was attributed to thrombosis of the axillary vein, but as it disappeared within a few days of the removal of the head of the bone, some other explanation seemed called for. Mr. Symonds called attention to the fact that the continued suppuration seemed due entirely to the cartilage covering the head of the humerus. This structure was found in a suppurating state, and was being thrown off by granulating tissue, and the moment the entire surface was removed recovery began, and was so rapid that, within a few days, he was up, and the parts nicely healed, the man getting flesh within three weeks. The supposition was that the complication was due to traumatic fever, which determined suppuration in the wound, and that this involving the joint structures, the cartilage, acting like a foreign body, maintained the suppuration. On these grounds, Mr. Symonds said he now always carefully removed all cartilage in operations

involving joints, for that while, in many cases, immediate union did occur, when the cartilage was left, an occasional result, such as the present, would happen. The man was shown to the Society two and a half years after the operation, and had a useful arm. He could do much of the lighter work of his trade of a carpenter, being able to drive nails and screws and use a plane. He was able to earn a good living. The rhomboid muscle acted well, having obtained a partial attachment, so that the man could throw both shoulders back. He could rotate the shoulder and carry it backwards and forwards, but was unable to raise it from the side. The tumor was a hard osteo-sarcoma, having a basis composed largely of fibrous tissue.

Reviews and Book Notices.

BOOK NOTICES.

A Compend of the Diseases of the Eye; including Refraction and Surgical Operations. By L. Webster Fox, M. D., etc., and George M. Gould, A. B. 12mo., 150 pp. 60 illustrations. Cloth, $1.00. P. Blakiston, Son & Co., 1012 Walnut street, Philadelphia.

Ophthalmology has made wonderful advances during the last fifty years. In the United States its progress has been upwards and onwards from the year 1820, when the first public institution for the free treatment of diseases of the eye was opened to the public in the city of New York. Since that time we have not only had numerous special hospitals, but some of the most brilliant results have been achieved in general hospitals. In these latter institutions, ocular diseases are treated as associated with other diseases of a chronic character. In the little work before us we have the results of the careful labors of two of our young ophthalmologists, giving a resume of the general principles and therapeutics of the subject. The authors dwell with much minuteness on the method of correcting errors of refraction and the fitting of glasses.

Part II. treats of functional disorders affecting vision, as paralyses, etc.

Part III. There is a very good account of the special diseases of the eye. Under the head of gonorrhœal ophthalmia, he employs the utmost cleanliness, reducing the inflammation by leeches with cold applications, and after the early stage of the disease has passed, he touches once a day with the mitigated solid silver nitrate stick. But he omits a very important agent in this fatal disease, as well as in ophthalmia neonatorum, the local application of cocaine, which reduces the intense congestion of the conjunctival vessels, and prevents ulceration and sloughing, as well as giving prompt relief to the ocular and circumorbital pain. Mr. Leahy, who first employed this treatment (*Indian Medical Gazette*, July, 1886), recommends a mixture composed of ½ grain of sulphate of atropine, and 4 grains of sulphate of cocaine, incorporated in 100 grains of vaseline. This mixture is introduced beneath the upper eyelids. In the case of young infants, the strength of the ointment must be reduced one-fifth, also the hydrochlorate can be substituted for the sulphate, and boracic acid for the atropine.

Part IV. is devoted to surgical operations on the eye, with admirable illustrations and some valuable statistics of operations from European and American ophthalmological institutions.

In the appendices we have a full list of formulæ, not omitting cocainæ hydrochloratis gr. x–xx, aquæ destillatæ f℥j, which we think is too strong for eye operations. It should not, we find, be more than gr. iv to f℥j of water, with an antiseptic, as it soon forms pencillium,* and nothing but fresh solutions should be employed in the eye.

With these slight omissions, we can most heartily recommend this hand-book to the student and general practitioner. The first will find in a limited space much valuable material, not only for study, but also for the practice of his profession.

A Generous Donation for the Promotion of Medical Science.

Edinburgh University has recently received a large donation from Dr. Gunning, of Rio Janeiro, to be used for the establishment of funds for prizes. The sum is large enough to establish eleven triennial prizes of $250 each. The prizes have received names which commemorate previous professors of the University. They are the Munroe Prize for Anatomy; the Bell Prize in Physiology; the Edward Forbes Prize in Zoölogy; the Hatton Balfour Prize for Botany; the Joseph Black Prize for Chemistry; the Christison Prize for Materia Medica; the Lister Prize for Surgery; the Gregory Prize in Practical Physic; the John Thomson Prize in Pathology; the Simpson Prize in Obstetrics; the Alison Prize for Medical Jurisprudence and Public Health.

*Hyphomycete, or mould.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

HYSTERIA IN CHILDREN.

Volumes and volumes have been written on hysteria, and an enormous amount of material, consisting of carefully reported cases of the disease, has accumulated, but of the variety occurring among children, especiallyyoung girls, comparatively little has been said. And yet hysteria, when attacking children, is a far more dangerous malady, and demands far more the closest scrutiny of the skillful physician, than the same complaint when met with in the adult. In the latter there usually is something about the patient that tells the doctor that he has a case of hysteria before him; but in children such rarely occurs.

Then the disease in the young is apt to simulate grave lesions of the brain, and the diagnosis, while naturally of great importance, if only for prognostic purposes, at times becomes difficult indeed. An article published by Dr. Inczek (*Berl. Klin. Woch.*, September 29,) and describing in detail two two cases of hysteria in children, is therefore, of great interest.

The first case concerned a girl æt. 9, who had probably inherited the disease, and want of education did the rest. The immediate cause was a trifling one, viz., sprain of an ankle. In consequence of too severe treatment, contractures first developed. Next trismus-like rigidity of the jaw set in, then various pareses made their appearance, and besides difficulty in swallowing and in speaking the patient suffered from local anæsthesia, insomnia, and psychical disturbances. The group of symptoms was grave enough to scare the uninitiated, for following an injury a traumatic lesion of the brain might well have suggested itself. But under anti-hysterical treatment the symptoms disappeared rapidly and completely.

The second case, a girl æt. 13, had been harshly treated. Though so young, she had been doing for four years all the work of a servant-girl, and especially the frequent washing near a large fire, which she had to do, seemed to have developed the disease. Besides, the child had been given comparatively very large quantities of miserable alcoholic drinks, apparently to prevent her from eating too much, as the woman, a real Satan, with whom she lived, had made the observation that such drinks diminished the child's appetite. Other causing elements could not be discovered.

The disease here was at once ushered in with psychical and motoric disturbances, tremor, palsy-like debility, difficulty of speech, differences between the actions of the two

facial nerves; later sensory troubles, hyperæsthesia, tenderness over the spinal column, symptoms of vaso-motor affection, paleness, low temperature, difference in the two pupils, trophic disturbances of the skin, and remarkable slowness of the pulse, all occurred almost at one and the same time, and made the poor child appear a very sick patient. Here also proper treatment in an institution rapidly brought about a perfect cure, and as I. notified the authorities, so that the child, when discharged from the hospital, came to people that treated her well, no symptoms of the disease had occurred up to date of report, nearly a year after her admission to the hospital.

In conclusion, I. lays stress on the well-known saying that it is not the medicine that cures hysteria, but the physician who does it.

STAINING OF TUBERCLE BACILLI.

Rapidly to prepare an anilin-water-fuchsin-solution, Dr. Saccharow (*Russkaja Med.*, 11, 1886, Russ.,) has discovered the following practical apparatus:

To a common holder with stand, as used in laboratories to keep reaction tubes, etc., in an upright position are attached:

1. A glass bottle with the bottom upside down and filled with anilin water. Whatever too much anilin is present accumulates in the lower part. Through the neck pass two glass tubes. One is intended to admit air, the other is provided with a piece of rubber hose and some little arrangement, as a clamp, for stopping the flow of the anilin-water.

2. A funnel and paper-filter, which fits into a glass tube just beneath the bottle, and which contains fuchsin-crystals, and has a pointed end.

3. Underneath this is another funnel and filter, through which the anilin-water, now containing fuchsin, gradually passes from above into a watch-glass, so that the solution is filtered the second time.

With this simple apparatus one may prepare at any time a fresh solution of fuchsin in anilin-water. As soon as the fluid is obtained the clamp on the rubber hose is closed, and the apparatus ceases working until the clamp is opened and the anilin-water allowed to flow out over the fuchsin again.

Though there still are a few skeptics who deny that microbes ever can be the pathogenic cause of disease, nobody disputes the importance of demonstrating the presence or absence of tubercle-bacilli in the sputa of a patient supposed to suffer from phthisis, but where the physical examination does not throw light on the case. These bacilli, however, so greatly resemble other microbes, that their staining is of the utmost importance. The apparatus above described greatly diminishes our labor, and thus facilitates the demonstration of the germs, when present.

The writer of this, not long since, attended a patient who four weeks before had contracted a bronchial catarrh. The man had always been in excellent health, and though he had been suffering from bronchitis previously, he never had felt so weak, nor had he lost as much in weight as during the last attack just mentioned. The most careful physical examination failed to reveal any other indication of lung disease, but tubercle bacilli were present in the sputa. About seven weeks later there was no doubt about the diagnosis—miliary-tuberculosis. The disease ran a very rapid course; for before the third month was passed, the patient was dead and buried.

FISSURES OF THE TONGUE.

In some people, especially where gastric disturbances are present, the tongue suddenly becomes fissured all over, without however becoming coated, changing its color, or losing its moisture. Prof. Schwimmer (*Wiener. Med. Woch.* 10, 1886,) had the opportunity to experiment on some cases at his clinic. Although he tried chromic acid, which had been recommended by Vidal, and though he applied iodoform, which Dr. Unna, a dermatologist of Hamburg, had greatly praised, in none of his cases the tongues evinced any improvement. If anything, they became worse, especially under iodoform. As the patients were greatly annoyed by this morbid state of their tongues, Prof. S. tried a series of remedies in the hope to bring about some alteration, but utterly in vain, even Kaposi's treatment with nitrate of silver was useless. Some improvement was noticed after the applications of soda solutions and the lactic acid, first employed by Schiff, gave the patients decided relief, and the latter in one case almost established a cure. Finally S. used papayotin, and the result was surprising. In every case an amelioration was at once noticed, and within a few weeks a perfect cure was obtained. S. applies the papayotin as follows:

℞.	Papayotin,	.05 to 1.0 (8–16 gr.)
	Aq. destill.,	
	Glycerin, āā	5.0 (80m).

This solution is applied with a camel's hair brush from 2 to 6 times every day after the parts have been previously well dried.

The effect is not a macerating one, as one would think from the action of the drug on digestion, but it acts by stopping the pain in the parts deprived of their epithelium, and causes a renewal of the latter.

In 25 cases, many of which were of many years' duration, a complete and permanent cure was established in all with the exception of one, where a syphilitic dyscrasia existed, but where specific treatment brought about no result either. But even in this case a great amelioration was obtained.

Notes and Comments.

Aseptic Surgery.

The President of the Sheffield Medico-Chirurgical Society, Dr. Cleaver, gave an address, October 14, on this subject, and laid particular stress upon the fact that many surgeons imagined they were practicing aseptic surgery, when, in reality, they were only treating with antiseptics, of which there were many methods, and all of them more or less imperfect, whereas, in aseptic surgery, there was only one method, namely—that introduced by Sir Joseph Lister, which aimed at, and attained, a complete absence of putrefaction, and is therefore designated aseptic. Another fatal error was that aseptic or Listerian surgery was spoken of as treatment by the spray. On the other hand, Sir J. Lister, in an address to the Surgical Section of the International Medical Congress in London in 1881, brought forward results of investigations he had made, tending to show that the atmospheric dust is not nearly so much to be dreaded as we used to assume, and that the various forms of virus are far more likely to be introduced by contact with infected liquids or solids than from the air. Dr. Cleaver had reason to believe that other considerations had confirmed Sir J. Lister's impression that, as a purifier of the air, the spray is of little value, and that, therefore, he used it less than formerly. It should be borne in mind that if the spray were not used, greater care was necessary in other respects. Dr. Cleaver claimed as one of the results of aseptic surgery complete immunity from infective disease, including pyæmia, septicæmia, erysipelas, and hospital gangrene, diseases which, twenty years ago, were rife in hospital practice. In upwards of 300 cases of major operations performed at the Sheffield Children's Hospital during the last few years, not one single case of these diseases had arisen.

Amputation for Senile Gangrene at the Age of Eighty-two; Recovery.

In consultation with Mr. Laurence Potts, of Leatherhead, in April, 1886, and again in July, Dr. James Cantlie had (*Brit. Med. Jour.*, October 30,) the opportunity of witnessing the progress of senile gangrene, commencing in the great toe of the left foot. The patient was an old lady, eighty-two years of age. She believed at first that a chilblain was affecting the toe; and, following the advice of her neighbors, she planted her foot in snow at various periods during the winter. As no improvement followed, she received further sage advice, and accordingly painted the toe freely with hydrochloric acid. When first he saw the case with Mr. Potts, gangrene of the great toe was fairly well advanced. Hypodermic morphine injections were being administered to relieve pain; and so bad was the nutrition of the limb that the punctures, where the nozzle of the syringe had entered at the affected (left) leg, remained unhealed for weeks. Temporizing measures were recommended; but, as the gangrene slowly spread to other toes and the dorsum of the foot, it was resolved that a Teale's amputation just above the ankle presented the only chance of doing any good. This was accordingly done. The parts healed up, and a well-nigh perfect stump resulted.

The advanced age of the patient was the only interesting circumstance in the case, combined with the indications of abeyance of the recuperative powers from the previous punctures not healing. The fact of age was brought more acutely home to him at the time, as, three days previously, he had operated on a case of strangulated femoral hernia on a woman seventy-nine years of age, in Charing Cross Hospital, and she made a rapid recovery.

Purpura Hæmorrhagica in St. Petersburg and Hamburg.

Dr. E. Masing compares (*St. Petersburger Medicinische Wochénschrift*, Nos. 39 and 40) a case of purpura hæmorrhagica of his own, together with 13 cases culled from the case-books of the Mary Magdalen Hospital in St. Petersburg, with the 73 cases collected by Dr. Scheby-Buch, from the records of the Hamburg General Hospital. Of the 14 Russian cases, 10 were complicated with pyrexia and 8 with diarrhœa. Eight presented painful and swollen joints and muscles, whereas in the 73 Hamburg cases only 27 are reported as having had rheumatic symp-

toms. Hemorrhage from the nasal and other cavities of the body occurred in 6 cases; *i. e.*, in about the same proportion as in Hamburg. Urticaria was not observed at all, though it was frequently present in the Hamburg series. Youth is the most common time for the disease to occur, 9 cases being under twenty-five years of age. The disease would appear to be even more rare in St. Petersburg than in Hamburg, for there were only 13 cases found in the Mary Magdalen Hospital Reports for the last twenty years, during which time the total number of patients was over 82,000; while the 73 Hamburg Hospital cases occurred in the space of forty-one years, out of a total of 100,000 patients. The mortality was greater than in Hamburg, 4 out of 14 being fatal in St. Petersburg, and only 10 out of 73 in Hamburg. One of the former series, however died of phthisis. The author is quite unable to throw any light on the etiology of hæmorrhagic purpura, but he expresses the hope that bacteriological research may help to clear it up.

Two Cases of Lupus Treated Successfully With Iodoform; Remarks.

For the following notes we are indebted to Mr. Guy Tyrrell, who publishes them in the *Lancet*, Oct. 30:

Case 1. Alfred R——, aged sixteen, was admitted to the hospital on Feb. 4, 1884, suffering from lupus of the nose and lip. The disease had existed for eighteen months, and had already destroyed the lower half of the alæ of the nose and almost the whole of the upper lip. The patient was ordered cod-liver oil, and the sore was dressed with an ointment consisting of one drachm of iodoform to one ounce of vaseline, plugs of lint covered with the ointment being inserted into each nostril. The sore immediately began to assume a healthy appearance and healed slowly but uninterruptedly, and the patient was discharged cured on July 29th.

Case 2. William V——, aged sixteen, was admitted on March 13, 1886. The disease had existed for two years, and extended over nearly the same area, but the lip was not so deeply involved. The same treatment was adopted, and with an equally good result. The patient was discharged cured on August 3d.

Remarks by Mr. Tyrrell.—I am inclined to publish these cases, as I do not know that this remedy has been tried before, not having seen it mentioned in any books; but the results in these two cases were certainly most striking, and I think it worthy of a further trial, as it is certainly a less painful method than scraping or cauterization.

Pelvic Hæmatocele.

Mr. Lawson Tait thus concludes an article in the *Lancet* (Oct. 30):

"We come, then, to the following conclusions: That in the great majority of cases of extra-peritoneal hæmatocele the disease may be left alone, being rarely fatal, and that it is to be interfered with only when suppuration has occurred. That, on the contrary, intra-peritoneal hæmatocele is fatal with such almost uniform certainty that so soon as it is suspected the abdomen must be opened and the hemorrhage arrested. In the overwhelming majority of cases the source of the hæmatocele will be found in the broad ligament, and then it can be dealt with, and with every prospect of success. If any one objects to this, I appeal again to the canon of surgery, which is of uniform application. For surgical hemorrhage cut down and tie the bleeding point; if a big branch of the femoral artery were bleeding, my colleagues who deal in such cases would cut down and tie it. Why should Poupart's ligament be a line of demarcation within which this surgical writ will not run? Why should my friend, Dr. ———, be allowed to do to the external iliac artery what I am prohibited from doing to the internal iliac division? Indeed, at page 202 of Bernutz and Goupil's work they assert this principle: 'The indication in such a case is plain—we must stop the hemorrhage.'"

Pouch of the Penile Urethra.

Before the Medical Society of London, October 25, Mr. E. Harry Fenwick showed a case of pouch of the penile urethra in a patient aged fifty-seven, who had suffered from stricture for the last eighteen years. The difficulty of micturition culminated in extravasation of urine a year and a half ago. Perineal incision was performed, and a large sac with several small facetted stones and one large one was removed. Urethral fever followed, but the man ultimately recovered. The pouch was probably due to distension of the canal behind an anterior stricture. It was proposed to pare the edges of the ante-scrotal sac at the same time that the bladder was drained through the perineum.

Mr. J. H. Morgan considered that Mr. Fenwick's explanation of the nature of the

pouch was correct. Instead of performing any cutting operation, he would be inclined to employ steel sounds with a view to dilating the strictures, and trust to the mechanical stimulus to improve the tone of the muscular coat.

Mr. Bruce Clarke thought something more than sounds and catheters would be required: excision of a portion of the urethra and joining together the cut ends.

The Infectious Capacity of Chronic Gonorrhœa.

Neisser, the discoverer of the gonococci, addressed the meeting of German physicians at Strasburg on the subject of the infectiousness of chronic gonorrhœa (*The Therapeutic Gazette*, September 15, 1886). He believes that the question whether chronic gonorrhœa is infectious or not cannot be answered summarily, but can solely be decided from case to case by repeated examinations of the gonorrhœal secretion for gonococci. Examining one hundred and forty-three cases of chronic gonorrhœa for gonococci, he found the proportion of cases giving a positive result to be almost equal to that giving a negative result. Neisser recommends, as the most effective treatment, nitrate of silver in a proportion of 1 to 3,000 to 2,000, or a five per cent. solution of salicylate of sodium, the remedy being best injected with a soft, thin catheter, having at its point several openings. In a case presenting, even on repeated examinations, no gonococci at all, treatment is better wholly avoided. The internal administration of the balsam of copaiba appears to be a useful measure. This recalls a statement of two French observers, Sinety and Hennegue, which is in opposition to Neisser's claim. In their experience injections of nitrate of silver were unable to kill the gonococci found in the urethritis of females. The same negative results they obtained also with permanganate of potassium, ozone-water, and even with corrosive sublimate.

The Treatment of Thread-worms in Children.

Dr. Sidney Martin writes as follows to the *Practitioner* of October, 1886:

The complete cure of thread-worms in children is often very difficult. While the ordinary methods used, such as rectal injections of salt and water, infusions of quassia, and other remedies, do good for a time, yet they often fail to relieve the attendant symptoms of "worms," symptoms usually very irregular, and in some cases severe, in character. In many cases, though the irritation about the anus is relieved by injections, the irregularity of the bowels and the disturbance of sleep remain the same. This is probably due to the fact that the habitat of the worms is higher up in the large intestine, where no remedy introduced by the rectum can reach them.

In many cases I have found that rhubarb in small doses brings away large numbers of worms, and at the same time regulates the bowels: so that the use of injections may in most cases be dispensed with. The formula which I have found most useful is as follows, varying slightly with the age of the child:

℞.	Tincturæ rhei,		♏iij.
	Magnesii carbonatis,		gr. iij.
	Tincturæ zingiberis,		♏j.
	Aquam,	ad.	ʒj.

This is to be taken twice or three times daily, according to the effect on the bowels. Whether the rhubarb acts as a vermicide or simply by "moving the worms on," I am unable to say.

The Term "Rheumatism."

In the course of a paper on rheumatism, read at the recent Berlin Congress of Naturalists and Physicians, Professor Senator, who adduced evidence to prove that rheumatism is a specific disease, made some remarks upon the popular acceptation of exposure to cold being a cause of disease (*Deutsche Med. Woch.*, No 41). He said that undoubtedly many painful affections of the locomotor system, many neuralgiæ and paralyses—e. g., facial—arise from sudden exposure to cold, especially if the surface be heated and bathed in sweat. But the term "cold" should only be applied to cases where the history of such exposure was quite clear, and the diseases produced thereby should be termed "refrigerant" rather than "rheumatic." The use of the words "rheumatism" and "rheumatic" should then be reserved for such cases of disease as are not due to mere cold, but to a special kind of miasmatic infection, like that which excites acute rheumatism—the prototype of rheumatic disease—and are amenable to specific treatment. Although this may be merely a matter of words, yet, as he truly remarked, correct nomenclature implies correct conceptions of the conditions named.

A Collection of Pine Leaves in the Bronchi Causing Repeated Hemorrhage.

Dr. Axel Key has recorded (in the *Lancet*) the case of a man, thirty-six years of age, who had suffered for seventeen years from

violent hemorrhage from the lungs. He died in the Serafim Hospital, December 1, 1885, after a short residence there. At the post-mortem examination the body was found to be robust, and not emaciated. In both of the larger bronchi there were a number of circumscribed blood coagula. The right lung was unaltered; in the left there was a slight enlargement of a smaller bronchus, with induration of the walls and immediately surrounding lung tissue. In the cavity of the dilatation there was a quantity of coagulum. Outside the cavity there were six pine leaves partly massed together, but with the points free; the leaves were of a brownish-gray, faintly changing into green, stiff, and with sharp points. The marks of the points appeared on the mucous membrane, and were several millimetres long. The lung was in other respects healthy. The leaves were, in the opinion of Dr. Key, the cause of death, owing probably to the fact that latterly they had embedded themselves more deeply in the lung, or that their position had changed to a new and more dangerous place.

A New View on the Causation of Bright's Disease.

At a recent meeting of the Académie de Médecine, Prof. Semmola, of Naples, brought forward, in an exhaustive paper, his peculiar views on the causation of Bright's disease. According to this inquirer, the nephritis which accompanies the malady is not primitive, but consecutive. Albuminuria is produced independently of alteration in the structure of the kidneys, and even, in his opinion, the real cause of the changes witnessed in those bodies is due to the constant passing of the albumen through their canaliculæ. Sufficient proof of this assertion might be found in experimenting on the lower animals. If the white of an egg was injected subcutaneously albuminuria was determined, and subsequently nephritis. On the other hand, the skin seems to undergo changes which are striking, and sufficient to account for the presence of the affection. The sweat-glands are atrophied, and the conjunctive tissue of the derma is very proliferous. He deduced from this that the skin was the first organ to be affected in Bright's disease, and not the kidneys, and all the attention should be turned toward that structure.

Shoemaker's Ulcer.

The *Brit. Med. Jour.* (Oct. 30) says that Dr. Danford Thomas has done well in drawing public attention to this peculiar form of industrial disease. While holding an inquest recently on the body of a shoemaker who had died suddenly at Queen's Road Station, Bayswater, from the bursting of an ulcer in the stomach, Dr. Danford Thomas said it was a pity that shoemakers persisted in pressing the boot to the stomach when engaged on their work, for the pressure was apt to produce an ulcer. We are informed by Dr. Lomas, an excellent authority on the subject, that a very large number of shoemakers suffer from stomach diseases. Some years ago an upright bench for shoemakers was exhibited by the Society of Arts, which, it is believed, is now used in many boot factories. The repairers of boots and shoes are the people who still carry on their work in the old way. In hospitals and dispensaries, he has met with some cases of hæmatemesis from pressure over the stomach. As a class, shoemakers are not healthy; many of them become very feeble at the age of 40 to 50.

Spontaneous Shedding of Nails in Hysteria.

Dr. T. Falcone, of Naples, records a case of hysteria, prolonged and aggravated, in the course of which there was spontaneous shedding of the finger and toe-nails (*Deutsche Med. Woch.*, Oct. 14th). The patient was fifty years of age,, and since 1870 had, after a mental shock, been subject to hemicrania and other nerve symptoms, including paraplegia, hyperæsthesia, globus, etc.. She recovered, but after remaining well for six years the symptoms returned on the occasion of her visit to the grave of her son, whose death had in the first instance been the exciting cause of her attacks. The affection of the nails was preceded by tingling in the fingers and toes, especially the thumbs and great toes, followed by suppuration in the bed of the nail. It was noted that on the right thumb the new nail was formed directly from the bed of the nail by proliferation of epithelium, which assumed a horny character; but on all the other affected fingers and toes the repair took place in the usual way, viz., by growth from the matrix. The condition altogether was regarded as a dystrophic one due to disordered nerve function.

Remarkable Tolerance of Opium.

At a meeting of the Société Médicale des Hôpitaux, M. Moutard-Martin mentioned the case of a patient, aged 50, suffering from tuberculosis, to whom he had given 45 cen-

tigrammes (4½ grains) of opium in progressive doses, without producing poisoning, contraction of the pupil, constipation, or dryness of the tongue. M. Rendu, who attended the meeting, suggested the advisability of giving the best quality of the extract of thebaine, in progressive doses, to the same patient; by that means it would easily be proved whether the man's tolerance of opium was not owing to the poor quality of thebaine dispensed in hospitals. Other cases were quoted at the same meeting by MM. Desnos and Sevestre of patients who had taken 2 grammes (30 grains) of morphine daily. In conclusion, M. Martin said that what appeared strange in the case of his patient was the fact of his being able to take the rapidly increased doses, from 20 to 45 centigrammes, in the course of five days.

A Specific and Prophylactic for Scarlet Fever and Diphtheria.

Dr. C. R. Illingworth thus writes to the *Brit. Med. Jour.*, October 30:

"In your issue of May 1, you inserted a communication of mine relative to the biniodide of mercury as a specific for scarlet fever and diphtheria.

"That it is a true specific for the former, is proved by the defervescence commencing immediately upon the administration of the medicine, instead of upon the fifth day, and by the absence of desquamation in consequence. That it acts as a specific in the latter, is shown by the rapid disappearance of the membranous effusion and reduction of temperature. The efficacy of the medicine depends, I think, upon the diffusible potassic iodide carrying the germicide biniodide to every portion of the circulation. Prescribed in this form, the biniodide of mercury has not, so far as I am aware, been used before for these diseases."

Lung or Liver?

The great difficulty in diagnosis that the physician has to contend with in the region that contains the right lower lobe of the lung and the liver, is one of the most patent facts of clinical medicine. And yet hardly a week passes that does not afford some illustration of the difficulty of surmounting even a well-recognized obstacle. M. Guyot has published a case of hydatid cyst of the liver which he mistook for a pleurisy of the diaphragm associated with pulmonary tuberculosis. It is said that all the physicians who saw the case were of M. Guyot's opinion. The hydatid cyst had suppurated, and the friction-sound was the result of spread of the inflammation to the serous surfaces. The rule laid down by many physicians, that the liver should be thoroughly explored in the presence of friction-sounds in the hepatic region, when there are the ordinary signs of suppuration, cannot be too strongly insisted upon.

A Case of Quinine Rash.

Dr. M. A. Veeder, of Lyons, N. Y., writes to the *Med. Record* that he has recently observed a case of quinine rash in which the condition of the skin closely resembled that existing in scarlatina. The patient, without consulting a physician, had for a day or two been taking quinine in small doses for some slight disorder, supposed to be malarial; but, becoming alarmed at the appearance of the rash, and imagining that the disease might be scarlet fever, medical advice was sought. The slight malaise and feverishness, together with the cutaneous conditions, formed a group of symptoms sufficiently obscure; but fortunately, for the credit of the profession, the source of the difficulty was at once suspected, and the taking of quinine foribdden. The rash disappeared with great promptness, but returned again repeatedly when, as an experiment, quinine was again administered in small doses.

A New Manifestion of Argyria.

M. Lewin has reported to the Berlin Medical Society his observation of an affection that seems to be peculiar to workers in silver. It appears in the form of round or oval bluish spots on the skin, which in extreme cases may be as large as a nickel five-cent piece, generally on the back of the left hand. Workmen in metals who do not use silver are free from it. The manner in which the spots are produced is not clear, for experiments with the direct application of silver in various forms have failed to generate them. The silver probably falls upon some scratch —for the spots are usually developed where there has been a lesion—in a solution, and afterward undergoes some chemical change by the action of the bodily fluids which induces this peculiar color.

Hæmatemesis in Hysterical Patients of Both Sexes.

M. Auguste Ollivier, of Paris, read an important paper at the Congress at Nancy on hæmatemesis in the absence of the catamenia. In cases of hysteria in both sexes hæmateme-

sis was met with, and appeared due to a special condition of the nervous system. He asserted that this variety of hæmatemesis, which was too often regarded as symptomatic of ulcer in the stomach, was, in reality, a form of local hysteria, with gastralgia, accompanied by hemorrhage. The absence of any disturbance of the nutrition, the suddenness of the onset, the presence of nervous disturbance, and the prompt re-establishment of health, would generally serve as indications of the true nature of the complaint.

Hernia of the Cæcum.

Mr. Frederick Treves read a paper on hernia of the cæcum before the Medical Society of London (October 18), in which he particularly called attention to the error which had crept into the text-books. It was generally stated to be devoid of a sac, but he had almost invariably found a sac to be present. Mr. Lockwood said that after an examination of many specimens in the museum of London and Paris, he had come to the same conclusion as Mr. Treves with regard to the sac. Mr. Sidney Jones wished to endorse the observations made by Mr. Treves, and added that the considerable volume of this kind of hernia was often an obstacle to reduction.

Cure of Rheumatic Tetanus by Pilocarpine.

Brünner describes (*Centralb. f. klin. Med.*, September 18, 1886,) the case of a peasant woman aged forty, suffering from rheumatic tetanus, whom he treated for five days without result, despite the administration of morphia, chloral, quinine, etc. Pilocarpine was then used in the single daily dose of one-third of one grain. The induced perspiration was moderate, but the increased salivary secretion was very great. Chloral hydrate was given at night. On the ninth day of treatment the convulsions disappeared completely.

Case of Paralysis Agitans, Apparently of Traumatic Origin.

To the Medical Society of London (October 25), Dr. Samuel West showed a man in whom peculiar tremors of the right arm came on immediately after a blow on the head. The symptoms had gone on increasing in severity for ten years, and now extended to the legs, rendering walking difficult. Sensation was diminished in the affected limbs, and he had occasional attacks of vertigo, but no distinct evidence could be obtained of any cerebral lesion.

Antipyrin in Pyrexia.

Brigade-Surgeon J. B. Hamilton, Medical Staff, Lucknow, communicates to the *Indian Medical Gazette* a paper on the above subject. His conclusions are that antipyrin is decidedly beneficial in reducing the temperature in cases of enteric fever, pneumonia, and insolation. In a few cases the drug was given subcutaneously. In no case did it produce skin eruption or vomiting. It acts well in children; but he would hesitate to give it to debilitated patients.

Cocaine in Gonorrhœal Ophthalmia.

A. Leahy recommends (*Indian Med. Gazette*, July, 1886,) a trial of cocaine in gonorrhœal ophthalmia. In his hands he has found that the ocular and circum-orbital pain is much diminished, the chemosis reduced, and the congestion of the conjunctival vessels much diminished. He used the following preparation: Cocain. sulph. 4 gr., atrop. sulph. ½ gr., vaseline 100 gr. To be applied with a camel's hair brush.

The Treatment of Felon.

Dr. W. H. Halbert is an advocate of the conservative treatment of paronychia. He treats it with salt and turpentine, allowing the mixture to remain on the finger several days, moistening the salt twice a day with the oil of turpentine. In the forming stage of a felon, he wraps the finger firmly with surgeon's silk isinglass plaster, and applies the mixture over it, leaving it undisturbed for two or three days.

A Substitute for Circumcision.

Mr. Herbert Snow, writing in the *Lancet*, suggests that circumcision may often be avoided by the introduction of a pair of dressing forceps under the prepuce, and stretching the skin by separating the blades. This can be accomplished without pain by means of an application of cocaine. After the tissues have been thoroughly stretched, the foreskin should be drawn back every morning for a few days.

—Irish moss, with one per cent, of cane sugar and two per cent. of beef peptone, is one of the cheapest and best culture media for micro-organisms, according to Dr. Alexander Edington, of Edinburgh.

Correspondence.

Convulsions.

Eds. Med. and Surg. Reporter:

On the 30th of June, Mr. A. sent after me to come and see his daughter, who he said was dying. She was 11 years of age. When I arrived I found her laboring under a very severe attack of convulsions, frothing at the mouth; and there was no possibility of administering medicines in any way. Applied cold cloths to her head, sinapisms to her wrists and ankles, and hot cloths to her feet. But the convulsions continued. We then put her into a tub of warm water and kept her in some 10 or 15 minutes, but owing to her convulsions the warm bath could not be satisfactorily administered, as any one who has had similar cases will imagine.

What now was to be done? My patient had been in convulsions four or five hours, and if anything getting worse instead of better, without the ability to take medicine. I then commenced to give her ether, and continued the inhalation until I had quieted her down; but as soon as the effect of the ether commenced to wear off, the convulsions commenced to return. What next? I put her again under the influence of ether until entirely quiet. I then injected hypodermically ⅛ grain of morphia in solution, and as my patient had a high fever, I immediately injected six drops of tr. veratrum, and as soon as the convulsions showed the least symptom, I renewed the inhalation of ether. In something like half an hour the symptoms of convulsions ceased, and the patient could swallow. I administered ten grains of bromide of potash, and ordered one to be given in two hours and a half after that. I took leave at 2 o'clock a. m., to return in the afternoon at 1 o'clock. When I returned she had had no more symptoms of convulsions nor fever, but had vomited every half hour for two hours. I applied mustard plaster over her stomach, and administered half-grain doses of calomel rubbed up in a little loaf sugar, until four grains were taken, which was indicated also otherwise. Vomiting soon ceased; she became conscious, and wanted to know what had blistered her wrists and ankles.

Connellsburg, Ind.

The Morals of Massage.

Eds. Med. and Surg. Reporter:—

On page 542 of the Medical and Surgical Reporter, October 23, 1886, I notice a statement made that "massage" is used for the purpose "of exciting the sensual feelings of the patients, or rather victims, and that the success of the professional rubber is closely connected with effects on the system in this direction." This you quote from the English journals. This may be so, but if it is, I think I am safe in saying that when massage accomplishes this purpose it is not performed properly, and will not only fail to effect any good, but do very much serious harm to the trouble one may be trying to relieve, and doubtless to the patient's morals also.

From an experience of several months on my own person with "rubbers" of various kinds, but well trained in their different teachings, I was able to confirm what I say above. Being of an extremely sensitive disposition, which was heightened by a long sickness, I was able to observe the effects with the greatest nicety. Whenever the rubbing consists of a friction of the skin, whether strong or light pressure be used, but especially the latter, the result is invariably more or less sexual excitement. This tends always to destroy any benefit one may have had from previous rubbings of the right kind. Desiring to gain all the good possible with the least expenditure of time, energy, and money, I performed a series of experiments to ascertain the exact value of different kinds of massage. I found that the deep, heavy pressure with rolling motion, so that the deep tissues were affected, with *scarcely* any friction of the skin, accomplished good results. My trouble was a muscular and nervous weakness of the bowels, in fact, complete collapse of those organs, arising from an aggravated constipation. I was obliged to desist from my experiments after having determined this point, as every time I neglected to follow the rules which I had laid down, I undid all the good which had been done by former rubs. I also arrived at some general principles regarding the locality in which the patient should be rubbed, but I cannot go into that here. In troubling you with these remarks, I can only say that I do not like to see the notice of an abuse pass without showing, if possible, that it is only an "abuse," for fear that popular prejudice may bring into disrepute a practice which in every way is worthy of our most attentive culture. The explanation of the fact I give, and which you also notice, is not far to seek for those who believe in some principle of "vital force."

F. B. Mickle, M. D.

A Remarkable Injury of the Finger.

EDS. MED. AND SURG. REPORTER:

I see in your issue of October 23 an article under the title of "A Remarkable Injury of the Finger." I had a very similar case about two years ago. A boy eleven years old fell from a ladder, and a ring upon his third finger caught upon a nail, stripping the coverings from the bone like a glove from the finger, as far as the third phalanx. The coverings contained the bone of the third phalanx, to which was attached the flexor tendon, which was pulled from its sheath in the forearm, and measured thirteen inches from the tip of the finger. The finger was amputated.

HENRY B. PALMER, M. D.

Phillips, Me.

NEWS AND MISCELLANY.

The Army Medical Service of France.

A recent return shows that on October 15 the strength of the French Army Medical Department (Corps de Santé Militaire) was 1,174 officers, and that there were on that date, altogether, 126 vacancies in the various grades, the strength sanctioned being 1,300 of all ranks. The numbers, according to rank, on active employ were: Médecin inspecteur général, 1; médecins inspecteurs, 9; médecins principaux, 1re Classe, 40; 2me Classe, 45; médecins majors, 1re Classe, 295; 2me Classe, 468; médecine aides-majors, 1re Classe, 208; 2me Classe, 108; total, 1,174. There were, in addition, 134 commissioned "pharmaciens" of various grades, on active employ in the army, with altogether 52 vacancies in this branch of the medical service. The "pharmaciens militaires" in the French service all hold a diploma, either of Master in Pharmacy or of Pharmacien of the 1st Class; some possess a university title of doctor, in addition to the 1st Class diploma of Pharmacien. The foregoing numbers show the strength of the medical department with the French army on active employment, but, beyond this establishment, there are two large bodies of medical officers, of different grades, borne on the rolls of the army of reserve, and of the territorial army of France.

The French Army in the East and its Hospital Service.

The French army of occupation of Tonkin and Annam has an effective strength of about 34,000 troops, of which number 15,000 are Europeans, 16,000 natives of Tonkin, and 3,000 natives of Annam. The army is organized as a division, divided into three brigades; and a certain number of hospital establishments are alloted to each brigade. The hospitals are of two kinds—fixed hospitals, organized on the ordinary regulation scale for field-service; and movable hospitals annexed to them, under the name of *infermeries ambulances*. There are altogether fourteen stationary hospitals, and twenty-five of the ambulance infirmaries. Owing to the nature and extent of the territory occupied by the troops, the difficulties in administering the hospital service have been unusually great; all the more so from the wide-spread and incessant demands made on the hospital establishments, and on the services of the medical officers, in consequence of the prevalence of remittent fevers of a severe type and other climatic diseases. The direction of the whole medical service of the army of occupation is in the hands of Médecin-Principal Dr. Dujardin-Beaumetz, whose headquarters are at Hanoï.

The Consumption of Alcohol in Belgium and Other Countries.

According to M. E. Laveleye, the consumption of ardent spirits in Belgium has nearly doubled in fourteen years, and is now surpassed only by that of Denmark and Russia. Everything is done to encourage it, as if drinking alcohol was a good thing, and one needing to be fostered by the State. The duty is only about 50 francs per litre, while even in France it is 200, and in England nearly 500. There is a place for the sale of drink to every forty-four inhabitants, or one to every ten families. What demon can be in possession of governments that leads them so to foster misery, crime, and poverty—to say nothing of disease? Such a licensed use of alcohol paralyzes and mocks all legislation for the improvement of the people, all social efforts, and all progress in medical science.

A Sensible View of the Temperance Question.

The *Medical Record* says that Dr. Huntington, rector of Grace church (New York), preached the temperance sermon in the Church of the Holy Trinity, Fifth avenue and 125th street. He said: "The Bible nowhere makes total abstinence necessary to righteousness, and it ill becomes advocates of total abstinence to maintain that any one cannot be really good unless he is a total ab-

tainer. Temperance does not mean total abstinence, but moderation. Yet it is true that, under the social conditions of this country, the cause of temperance can best be served by the adoption of habits of total abstinence. The remedy of the widespread evils of drunkenness can best be secured by the quiet method of personal example and influence, rather than by noisy and demonstrative parade. I am not one of those who expect that legislation is going to effect a remedy of the evil. We must look to the personal example of abstinence set by men for the benefit of their weaker brethren, to gradually reduce the pitiable evils of intemperance." Well said, Dr. Huntington! Science, morality, civilization, and religion, are on your side.

Unusual Coincidence.

On the 18th of last month a man and his wife were admitted into St. Thomas's Hospital (London), suffering from acute pneumonia of respectively three and four days' duration. Each was aged thirty-two years. The disease ran an acute course, being little influenced by treatment, and they died at the end of four days, within a few hours of each other. At the post-mortem examinations, which were made on the same day, acute inflammation of the right lung was found in each; this had attacked chiefly the base in the case of the man, and the apex in the woman. It would appear that they had left their house and moved into lodgings only two or three days before the commencement of the disease, on account of the bad smells, making it probable that the disease was of septic origin.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE WEEK ENDED NOVEMBER 13, 1886.

Ames, R. P. M,, passed assistant surgeon, To proceed to Vineyard Haven, Mass., as inspector, November 10, 1886.

Urquhart, F. M., passed assistant surgeon. Granted leave of absence for seven days, November 8, 1886.

Wasdin, Eugene, passed assistant surgeon. Granted leave of absence for seven days, November 11, 1886.

Magruder, G. M., assistant surgeon. Relieved from duty at Norfolk, Va.; assigned to duty at Marine Hospital, Chicago, Ill., November 10, 1886.

A Curious Wager.

The following is extracted from the *Indian Medical Journal* for July: "Two Mahometans in Hyderabad City made a curious wager the other day, which resulted in the death of one of them. The deceased accepted a challenge that he would stand facing the sun from 8 a. m. to 6 p. m. A certain day was appointed, when a large gathering assembled to witness the *tamasha*, as they styled it. The deceased took his stand, gazing at the sun from the agreed time up to 3 p. m.. when suddenly he dropped, foaming from the mouth. Medical aid was soon summoned, but before assistance arrived life was extinct.

Poisoning by Ptomaines.

Two deaths are again recorded, believed to be due to the formation of alkaloidal poison in the arrested putrefaction of smoked meat. Two women, at Bangor, in the north of Ireland, were recently seized with all the symptoms of irritant poisoning, which terminated fatally. The whole of the family partook of German sausages, and all suffered subsequeutly from vomiting and diarrhœa. After a thorough investigation, the result arrived at was, that death was due to the development of poisonons alkaloids in the Oerman sausages, of which the whole family had partaken.

Republican Austerity.

Dr. James R. Chadwick, who was delegated to represent Harvard University at the recent festivities at Heidelberg, tells a story of the "republican austerity" which he was supposed to illustrate. For while other delegates presented their credentials emblazoned upon parchment, and enclosed in cases of velvet and gilt, all that he had to offer was an informal note, written on a half-sheet of paper by President Eliot, and bearing date at his summer residence at Mt. Desert.

The Pasteur Institute.

M. Pasteur now finds, it is stated, that the 2,000 square metres of ground, of which the city of Paris has granted him the free use for ninety-nine years, are insufficient for his purposes. The plan for his future institute is said to be an ambitious one; and he, therefore, asks the Municipal Council to let him have a large plot of ground adjoining his allotment, for which he is willing to pay. It is thought that M. Pasteur will obtain it at a rent scarcely more than nominal.

Nitrate of Silver Stain.

Dip the fingers into a strong solution of cupric chloride. In about a minute the silver will be converted into chloride, and may then be washed off with hyposulphite of soda solution.

Personal.

—Dr. J. R. F. Bell has removed to No. 2028 North Broad street.

—Dr. F. B. Hazel has removed to 841 North Broad street.

—Dr. Charles S. Turnbull has removed his office and residence to 1719 Chestnut street.

Items.

—The British Medical Association have decided to hold their annual meeting for 1887 in Dublin, and Dr. J. T. Banks, Professor of Physiology in the University of Dublin, is the president-elect. The meeting will be held on August 2, 3, 4, and 5.

—It is stated by a St. Petersburg journal that the first experiences of the Odessa Pasteur Institute have been far from encouraging, five patients having died out of a very moderate number treated by Pasteur's method.

—Some one has discovered certain points of similarity between a baby and a widower: He cries a great deal the first three months; after this he becomes quiet, and begins to notice; and it is with considerable difficulty that he is made to survive his second summer.

—The friends of Charles Robin have opened a subscription list, in order to obtain the funds necessary for the erection of a monument to his memory. Quite a sum has already been collected, the subscriptions running from five francs up to five hundred francs.

—The Memphis City Hospital is a very poorly-conducted institution, according to the *Mississippi Valley Medical Monthly.* The mortality rate is high (nearly fourteen per cent.); the wards are not well built, and are not kept in a cleanly condition. The cause is want of money.

—By the use of cotton filters and respirators Dr. David Prince, of Jacksonville, Ill., proposes to keep the infectious germs from spreading out of an infected room and from entering the system of persons exposed. Cotton filters arrest the passage of all particulate matter.

—Intelligence has been received of the existence of an epidemic of small-pox at Kingston, Jamaica. On the 13th ult. there were no fewer than 362 cases under treatment, and the deaths had been exceptionally numerous. The inhabitants were leaving the town in very large numbers, as the disease was rapidly increasing.

—The medical advantages of Vienna now lie mainly in the departments of dermatology, laryngology, and venereal diseases, says a correspondent of the *Cleveland Medical Gazette.* The two leading men in the second branch, named Schnitzler and Schrötter, have only four vowels between them, to make up for which there is a regular inebriism of consonants.

—Paralytic ataxia of the heart is the name given by Prof. Sammola to a cardiac neurosis which comes on at the age of forty to sixty, as the result of emotional strain and venereal excesses. It is characterized, first, by severe dyspeptic troubles, then by cardiac symptoms, palpitations, and irregular heart action, marbled extremities, dyspnœa, and slight œdema.

—A pale, cadaverous-looking Irishman entered a doctor's office, and with both hands pressing heavily his right chest, in much agitation addressed the medical man in a whisper as follows: "Doctor, I'm in a very bad condition; my right lung is clean gone, and I have lost my voice entirely," then changing both hands to the opposite breast, he continued, in a loud, clear voice, "but this lung is all right, doctor."

—At the annual meeting of the American Rhinological Association, held at St. Louis, October 5, 6, and 7, the following officers were elected:

President.—J. A. Stuckey, M. D., of Lexington, Ky.

First Vice-President.—Carl H. von Klein, M. D., of Dayton, O.

Second Vice-President.—Theodore North, M. D., of Keokuk, Ia.

The Association adjourned, to meet on the last Tuesday in September, 1887, at Dayton, Ohio.

QUERIES AND REPLIES.

THE ROTTING INFLUENCE OF A DRY CLIMATE ON RUBBER GOODS.

EDS. MED. AND SURG. REPORTER:

Can you, or any of the readers of the REPORTER, tell me how I may prevent the effects of this dry climate on rubber goods? All my catheters and rubber tubing of every description, dry, crack, and rot, after keeping them a short time in th s climate. Elevation, 6,000 feet.

Arizona Territory. W. N. SHERMAN, M. D.

Pallas Syringe."

[From the *London Medical Record.*]

SOLUBLE
PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

105-15556

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease-producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE.

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

Lecture.

A CLINIC ON HEART DISEASE.

BY STEPHEN SMITH BURT, M. D.,

Professor of Physical Diagnosis, New York Post-Graduate Medical School and Hospital.

Because of the close proximity of the valves of the heart to one another, the sounds and the murmurs are best distinguished at points somewhat removed from their origin. These positions are found in the direction of the blood current, and also where the heart approaches the surface of the chest. Cardiac sounds must be dissociated in your minds from heart murmurs. Sounds are normal, and therefore audible in health, while murmurs are abnormal, and hence occur only in disease. Heart sounds, it is true, may be heard in disease, but they are then modified in quality. The place selected for listening to aortic sounds is close to the sternum in the second right intercostal space; for the pulmonary sounds, at the left edge of the sternum in the same relative position. Sounds from the mitral valve are conducted to the left apex, and those of the tricuspid valve are best heard just over the ensiform cartilage. Here are the points of maximum intensity, not only of heart sounds, but also, with few exceptions, of valvular murmurs.

Now, what is the accepted explanation of the mechanism of heart sounds? The first sound, which is synchronous with the apical impulse, is produced by closure of the auriculo-ventricular valves, by contraction of the muscular fibres of the heart and by the impulse of the organ against the chest. The second sound is due solely to the sudden closure of the aortic and pulmonary valves. First a sound, then a short silence, followed by a second sound, and then a longer silence, comprise rhythmic cardiac action. Both these sounds are audible at the apex, and both are heard also at the base, but in the former instance the accent is upon the first, and in the latter upon the second sound. In order to fully appreciate this cycle of the heart's action, let me give you in a few words what is taking place within the organ. While blood is being thrown from the right ventricle into the pulmonary artery, and from the left ventricle into the aorta, the auricles are filling. Then upon closure of the aortic and pulmonary valves, blood flows passively into the ventricles; and, just before the first sound of the heart, auricular systole drives the remaining blood from the auricles into the ventricles, which in turn propel it onward, the one into the pulmonary and the other into the systemic circulation.

I shall first present to you a man whose heart is unaffected, so that we may have a standard for comparison. The same methods serve to explore the heart that are employed in examination of the lungs. By inspection we see the impulse of the apex in the left fifth intercostal space, about two inches from the sternum. Pulsation is sometimes noticed in the epigastric region, which may not be abnormal. It is not necessarily incompatible with health for the apical impulse to be absent. The position of the apex can then be determined by auscultation. Palpation enables us to detect the force of the heart's impact against the chest. Mensuration would give the actual distance of cardiac enlargement or of displacement.

By thermometry we decide between acute and chronic heart affections; there is no fever in the latter. Percussion defines the limit of præcordial flatness and of dullness. As I percuss from above downwards one inch to the left of the sternum in the parasternal line, there is a rise in pitch that amounts to dullness at the lower border of the third rib, which changes to flatness at the lower edge of the fourth rib, and thus continues into the left hepatic area. Beginning at the outer side of the left nipple line, on a level with the fourth rib, to percuss towards the sternum, there is dullness just at the inner side of that line which extends to the border of the lung, and flatness thence over the superficial area of the heart as far as the sternum. The area of dullness shows where the heart is covered by lung tissue. Percussion in health to the right of the sternum and over that bone is unsatisfactory. But having located the apex and defined the upper and left borders of the heart, and knowing that the right border extends about one inch to the right of the sternum, we are able to delineate the position of the organ well enough for all practical purposes. On placing the stethoscope over the apex, which is the mitral area, I hear a dull, prolonged tone, low in pitch, and accentuated; this is followed by a brief pause, and then by a short, sharp, high-pitched note, that in turn is succeeded by a somewhat extended silence.

This is the circuit of one cardiac revolution, with systole and diastole as heard in the mitral region. Next adjusting the instrument to the aortic area, the second right intercostal space, those two sounds are again heard, and with rhythm unchanged, but with the accent transferred from the first to the second sound. Apical impulse is synchronous with the heart's first sound, yet when there is no perceptible shock, the first sound can be determined by placing the fingers upon the carotid artery, which pulsates also in synchronism with cardiac systole. Enlargement of the heart increases the superficial area of the organ in the direction of the enlargement. With hypertrophy the impulse is forcible and somewhat concentrated; in dilatation it is weak and diffused. From dilatation the first sound loses its muscular element, and is, therefore, short and sharp like the second sound. In hypertrophy there is intensification of the first sound, and the second sound is accentuated by the increased pressure on the valves at the base of the heart. Finally, the first sound is weak in all diseases that cause failure of the contractile power of the ventricles.

Changes in the valves that cause either obstruction or patency, or both, give rise to murmurs, but all murmurs of the heart do not necessarily indicate lesions of the valves. And, too, now and then the valves are seriously affected without producing murmurs. A murmur may be due to simple roughening of an orifice, or of a ventricular cavity; and, moreover, to a perverted muscular action as well as to spanæmia. It is far easier to detect these murmurs than to determine their import, and I can not too emphatically impress upon you the importance of a scrutiny of the heart cavities for the full explanation of what a murmur means.

If there is one with systole at the aortic orifice due to obstruction, there will be hypertrophy of the left ventricle. If one in diastole, there will be dilated hypertrophy of that ventricle as a result of the regurgitation. Insufficiency of the mitral valve has a systolic murmur, and gives rise to enlargement of the left auricle, right ventricle, and eventually of the whole organ. Obstruction at this opening develops a presystolic murmur, and results in enlargement of the left auricle, right ventricle, but not of the left ventricle.

Having discovered a murmur over the heart, the first thing to do is to locate its point of maximum intensity, and next its area of diffusion, and then to determine its rhythm. A valvular murmur takes the place or part of the place of a sound, or precedes it. Aortic systolic murmurs have their point of greatest intensity in the right second intercostal space close to the sternum, and their area of diffusion upwards. Mitral systolic murmurs are heard best at the apex, and are carried to the left and often through the chest to the back, near the lower angle of the left scapula. An aortic diastolic murmur is usually heard plainest at the second right intercostal space, and extends both upwards and downwards. Its point of maximum intensity, however, is not infrequently at the lower end of the sternum.

Murmurs of mitral obstruction are loudest a little above the apex of the heart, and are not widely diffused. Those of tricuspid insufficiency are systolic in time, most pronounced at the lower end of the sternum, and are carried upwards to the right, though not far. Lesions of the pulmonary valve are extremely rare, and need not occupy our attention at present.

Some of the exceptional points in regard to the heart, its position and murmurs, shall be considered another time. It will suffice for to-day if I make clear to you a few lead-

ing facts respecting the subject of heart disease: That murmurs have but a relative value, and depend upon the condition of the heart walls for their solution. That lesions are constant, while murmurs are not. That some lesions are progressive and others are stationary, and that it is not so much the valve as the integrity of the heart-muscles which concerns us.

With these things in mind let me present a patient for your consideration. Five years ago he had an attack of articular rheumatism. Since then he has complained chiefly of shortness of breath on extra exertion, followed by a slight dry cough, with now and then attacks of flatulent dyspepsia. While all articular rheumatism is not complicated by endocarditis, nor every case of valvulitis the result of that disease, still a damaged valve can often enough be traced to rheumatism to make pertinent an inquiry for that malady. Now, of valvular lesions that of the mitral is most commonly the cause of shortness of breath on exertion, and it is also the oftenest affected by inflammation in rheumatism. Hence we are naturally led to suspect this valve. The apical pulsation is a little below and beyond the ordinary position, and the impact is strong. Too much tissue overlies the cardiac region to enable us to demonstrate, satisfactorily, by percussion, a slight increase in the size of the heart. Auscultation reveals a soft blowing murmur whose greatest intensity is over the apex of the heart, and diffusion to the left. It is audible near the lower angle of the left scapula. Its rhythm is systolic, and it takes the place of the mitral first sound—a mitral systolic murmur. There is no resulting tricuspid affection. Pulsation in the radial artery is neither weak nor irregular. The muscular tone of the heart is good. Apparently little enlargement of the organ has taken place. It is mitral insufficiency, but in my opinion the disease is not progressing. Our patient probably had an acute valvulitis with his articular rheumatism. The scar of that inflammation remains, but the enlarged heart muscles compensate the insufficiency of the valve, so long as he does not over-exert himself.

Consequently, the prognosis is favorable, providing he follows our advice respecting his mode of life. He must not undertake violent exertion, any more than he would were he lame elsewhere than in his heart. A mixture of rhubarb and soda, including five minims each of the tinctures of nux vomica and digitalis, taken three times a day before meals, will help correct his stomach difficulty and restore the passing disturbance of the balance between his venous and arterial circulation.

The condition of this patient teaches us that the presence of a valular lesion need not necessarily cause alarm. He may live a great many years, and sudden death never happens from disease of the mitral valve. Even in aortic insufficiency, which may justly excite apprehension, it is surprising how long adequate compensatory hypertrophy lasts when properly managed.

COMMUNICATIONS.

TRIAL SPECTACLE FRAMES, AND THEIR DEFECTS.

BY LOUIS J. LAUTENBACH, M. D., PH. D.,

Assistant Surgeon to the Eye and Ear Department of the Philadelphia Dispensary.

Trial spectacle frames should have graduated carriers for three pairs of glasses, the distance between them being sufficient to allow of the use of the stronger lenses when necessary. These carriers should be so arranged as to permit the use of handles on the cylindrical lenses; they should be adjustable both for pupillary distance and for the height of the nose; they should be so arranged that the glasses can be placed not only parallel to the facial plane, but also at slight angles thereto:—the glasses ever being in a plane at right angle to the visual line (this is of considerable advantage in the testing of near vision); they must be of light weight if their pressure is borne by the nose; they must have a secure method of attachment, adjustable for different heads, which will not be attended with too much inconvenience, nor occasion unpleasant pressure.

Of trial frames there are a great number of varieties, all of which have marked defects. The most usual defects are great weight and a difficulty of adaptation to the patient's face; the frame requiring to be adapted to the width of face, pupillary distance, and height of nose.

Fig. 1 represents the common double carrier frame; is not adjustable, is however of light weight; handled cylinders cannot be used.

The Nachet frame is adjustable for height of nose and for pupillary distance; it will hold cylinders with handles; it cannot be placed at angles with the facial plane (as is necessary in near vision); its great weight, and the impossibility of fitting it on children,

Fig. 1.

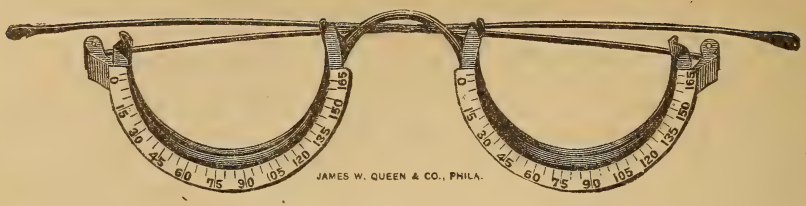

Fig. 2.

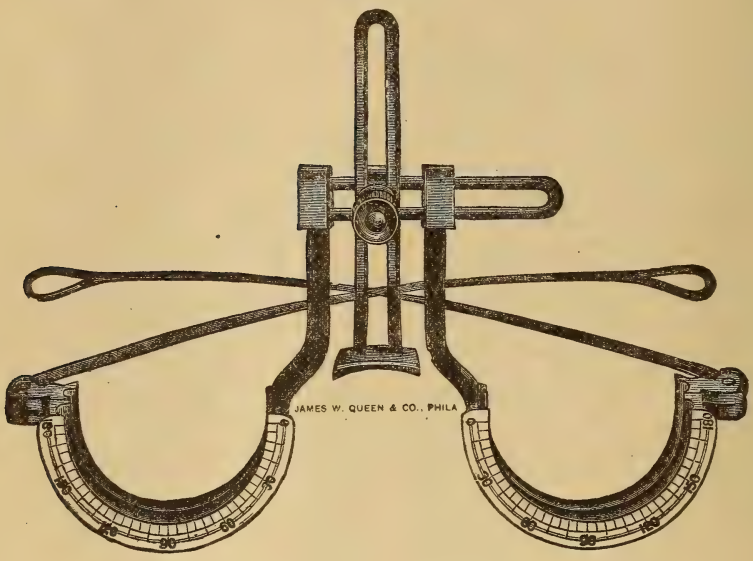

Fig. 3.

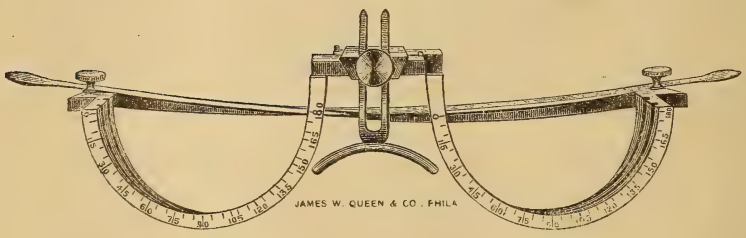

Fig. 4.

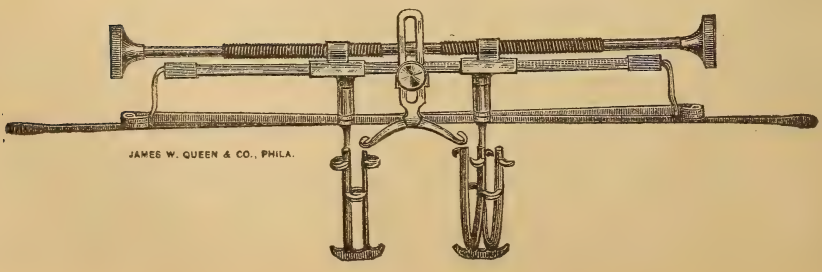

FIG. 5.

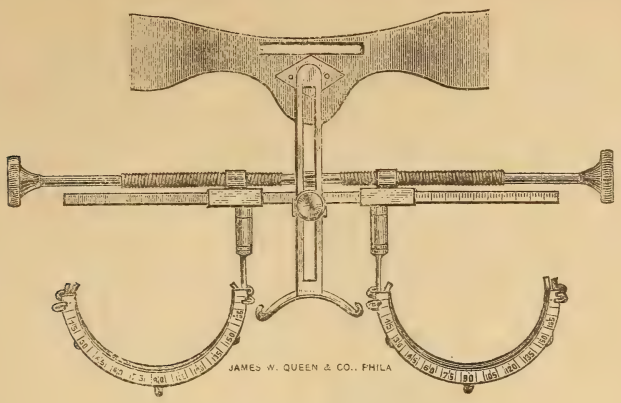

FIG. 6.

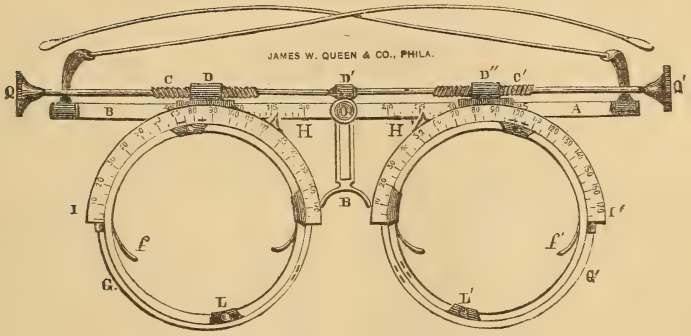

FIG. 7.

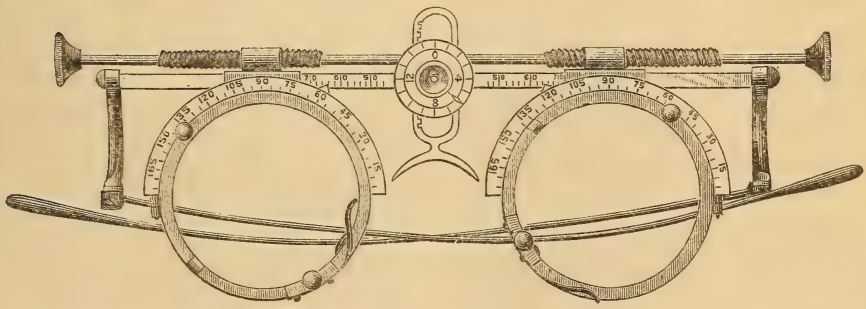

well-nigh preclude its use. There is now being used a frame made after the Nachet pattern, its carriers however being fixed, which is of very light weight, but otherwise has the same defects.

The English Hospital frame (Fig. 2) is adjustable both for eye-distance and nose height; it cannot be used satisfactorily for the testing of near vision, nor can it be used with accurateness upon children; its weight is a disadvantage; cylinders with handles cannot be used.

The Randall frame (Fig. 3) has the disadvantages of the last-mentioned, but is decidedly lighter in weight. This frame has, unlike the other frames so far mentioned, three pairs of carriers.

The Ivan Fox modification of the Randall frame allows the use of the handled cylinders.

The Wallace modification of the same frame has the same defects, but it has a ready means of varying the pupillary distance, and also the height of the nose-piece,

otherwise it labors under the disadvantages of its parent.

The Fox frame (Fig. 4), with straight sides, is not heavy, but yet remains on the nose with great difficulty. The forehead nose piece (Fig. 5) overcomes this; but both have the disadvantage of not being valuable for children, not being secure even on adults, nor yet allowing accurate testing of near vision.

The Armaignac frame (Fig. 6) has its sides arranged with a hinge joint, to allow of the glasses being worn at right angles to the visual line, but practically this is not satisfactorily accomplished. It has otherwise the defects of the Nachet frame.

The Meyrowitz frame (Fig. 7) has the advantage over the last-mentioned of lightness, and a quick adjustment of the nose-piece, but otherwise has its defects.

The frame of the Geneva Optical Co., which has a screw adjustment for pupillary distance, and a method of fixing the glasses in a plane at right angles to the visual line, has apparently all the disadvantages of the Armaignac frame.

The frames mentioned are the most important of the many, and yet they all have very serious defects. For use, the Wallace modification of the Randall frame, and Dr. Fox's frame with strong side-pieces, are the most valuable. Of the frames allowing of the inclination of the plane of the glasses, the Meyrowitz may be considered the most satisfactory.

A PARTIAL STUDY OF THE SEASONAL RELATIONS OF CHOREA AND RHEUMATISM.*

BY MORRIS J. LEWIS, M. D.,

Of Philadelphia.

The present paper is based upon a study of the seasonal relations of chorea and rheumatism, and for this purpose the weather at Philadelphia, for the years 1876–1885 inclusive, has been investigated, together with the number of storm-centres, or centres of low barometer, passing across or near the United States. These data were obtained from the monthly weather reports, and from the records kept at the signal station in this city, which have been kindly placed at my disposal.

Recent investigations undertaken by me in 1881, in regard to the relation existing between the number of cases of chorea and the varying states of the weather, showed such a curious resemblance between the chorea and storm-tracings that I deemed the subject worthy of further study.

The former work is embodied in Dr. S. Weir Mitchell's book of *Lectures on the Diseases of the Nervous System, Especially in Women*, and the statistics there mentioned were based upon the study of the months of onset of 170 separate attacks of chorea occurring in the years 1876–1880 inclusive, but at that time the storm records of the years 1878–1880 inclusive only were available, during which time 87 of the above-mentioned 170 attacks occurred. For the present study I have collected all the separate attacks of chorea which have been noted at the clinics of the Orthopædic Hospital and Infirmary for Nervous Diseases during the years 1876–1885 inclusive. These number in all 437, and necessarily include those previously studied.

As it is a well-recognized fact that a relationship exists between chorea and rheumatism, which, it is needless to say, is as yet imperfectly understood, I thought that it would be of much interest to compare with the cases of chorea the months of onset of attacks of acute inflammatory rheumatism occurring during the same period, and for this purpose have carefully studied the notes taken at the Pennsylvania Hospital, which have been placed at my disposal; from these I have collected 467 separate attacks of rheumatism, having excluded those that are at all doubtful, and those which occurred among sailors at sea, who were afterward brought to this port.

It must be borne in mind that while the records of the weather are complete as far as they go, the cases of disease here reported are but a small portion of those that must have occurred in this city during that decade; but, despite this fact, there is every probability that the percentage of chorea cases per month is practically correct, as may be seen by the almost exact resemblance between the two tracings of 170 and 437 attacks, respectively; Nos. 3 and 5.

To study properly the effect of the weather upon disease, there should be a *daily* record of both weather and disease taken, as has been so carefully done in the relation of pain to weather by Captain Catlin, recently reported by Dr. Mitchell before the College of Physicians (*Transactions of the College of Physicians of Philadelphia*, vol. vi.). In the diseases in question, however, the *day of onset* could only be obtained with certainty in

* Read before the Philadelphia Neurological Society, October 25, 1886.

a few cases, and, therefore, it was necessary to be satisfied with the *month of onset;* this, of necessity, destroys, to some extent, the value of the observations, but sufficient of interest remains to justify the present study. By taking the average of too long a period of weather the effect of sudden changes and all irregularities are lost sight of, and in this way some facts of importance may be overlooked.

In the present study the monthly average of the weather has been taken and compared with the monthly averages of disease, but the peculiarities about to be spoken of are best seen when a table is made which shows the mean of the ten years in question month by month.

The accompanying table* is so arranged by repeating the first half of the year, that any portion of the tracings may be studied in unbroken sequence.

Tracing No. 5 represents the *months of onset* of 437 attacks of chorea, and shows the actual number for each set of months, or the average number for each set, according to the manner of reading the figures; thus, January shows 36 attacks, which means 36 attacks for the ten Januarys, or 3.6 cases as an average for each January.

This tracing will be seen to be lowest in October and November, 18 and 19 attacks respectively (4.1 and 4.3 per cent.); it then rises rapidly, until 36 attacks in January have been reached (8.2 per cent.), falls slightly in February, and again rises, reaching its highest point in March, which shows 67 attacks (15.3 per cent.); the line then falls in April to 38 attacks (8.6 per cent.), and after two more rises—one in May, 47 attacks (10.7 per cent.), and the other in July, 46 attacks (10.5 per cent.)—falls almost perfectly regularly to its lowest point in October. Before attempting to find an explanation for the high percentage in March, I will again draw attention to tracing No. 3, which represents the 170 separate attacks previously reported; this will be seen to resemble, in every essential particular, the tracing we have just studied. These cases I have included in the present paper. Nothing especial is seen in comparing with the chorea tracing, that of the *mean relative humidity* (No. 9), or that of the *mean barometer* (No. 2), except that there appears to be an increase in the number of attacks of chorea with a fall of the mean relative humidity and barometer tracings; neither is much seen in comparing with it the mean daily range of the thermometer (No. 1), which shows the variableness in temperature of the different months; this is greatest in May, and least in December.

A resemblance begins to be apparent between the chorea tracing and the tracing of cloudy days (No. 7). The mean temperature tracing (No. 4) does not throw much light on the subject.

The tracings of the number of days on which rain or snow fell, and that showing the amount of rain or melted snow in inches, also show a slight resemblance to the chorea tracing. These lines are not shown on the table.

The probable cause of the resemblances noted becomes more apparent when the storm tracing is studied, because these meteorological factors may be considered as component parts of a storm.

Tracing No. 8 represents the number of storm centres (or centres of low barometer) passing within a circle of 400 miles radius described around Philadelphia as a centre.

In studying the storms, circles of varying radii were thus drawn around Philadelphia, and the number of storm centres, as marked on the weather bureau maps, counted in each; but the closest resemblance appeared to be with the number of storms passing within the 400-mile circle, and for this reason it is the only tracing that I have placed on the table. In the former study, the great resemblance between the chorea tracing and the storms within the 750 mile circle was pointed out, but the result of the present study, being more exact and more extended, is the one to be the most relied upon.

The small number of storms passing within the 400-mile circle occurs in August; a rapid rise of the tracing then takes place until December and January is reached, then there is a slight fall in February, immediately followed by a rise to the highest point in March, after which there is an irregular fall until the low point in August is reached.

Any one looking at these two tracings, as shown in the table, will have to acknowledge that the marked resemblance which exists is more than accidental; but to decide which factor in this complex disturbance, which we call a storm, is the baneful one, or in what manner it acts, is difficult.

Let us now turn to another disease, and study its tracing, and for this purpose acute articular rheumatism has been selected, on account of its well-recognized relation to chorea.

Line 6 represents the months of onset of

* As the essence of the table is given in the remarks, we have left it out to economize space.

467 separate attacks of this affection, and, like the chorea tracing, represents the actual number for each set of months, or the average per month.

November shows the fewest attacks, viz., 24, or 5.1 per cent.; from this point the tracing rapidly rises until January, with 50 attacks (10.7 per cent.) is reached, then falls slightly in February and March, to rise to its greatest height in April, 81 attacks (17.3 per cent.); from this point it rapidly falls to 32 attacks in June (6.8 per cent.), and then gradually and slightly irregularly falls to its lowest point in November.

While the chorea tracing shows a strong tendency to keep pace, month by month, with the irregularities of the storm tracing, that of rheumatism, while also strongly resembling the latter, may be seen to be exactly *one month later*, looking as if the effect of the meteorological changes was immediate in the case of chorea (as it is now acknowledged to be in some varieties of neuralgia), and preparatory only in the case of rheumatism.

From the close relationship known to exist between these two diseases, one might be led to suppose that the rheumatism tracing would precede, or at least accompany that of chorea, instead of following it, as this study seems to show.

In Zurich, according to Lebert, as quoted by Senator in Ziemssen's Clyclopædia, out of 220 cases of rheumatism during the years 1853 to 1859, the highest percentage occurred in January, 9.5 per cent., and in April, 13.3 per cent., agreeing exactly with the months of highest percentage in this city. A study of the storm records abroad, and their relations to rheumatism and chorea, would be interesting, and probably explain the seeming diversity of opinion.

Many of the statistics of chorea are of but little value in this connection, as the months of application for treatment, and not the months of onset, are given.

The reports of observers in different countries do not agree as to the season of the year in which chorea is most prevalent.

Angel Money (*Brain*, 1882, p. 512) reports the *months of application for treatment* of 224 cases to University College Hospital, and to the Hospital for Sick Children. The greatest number occurred in January, viz., 30 cases, and the smallest number in July, August, and September, viz., 11 cases each. Arranged according to seasons, spring shows 70, summer 47, autumn 44, and winter 63.

Germain Sée (*De la Chorée*, Paris, 1850, p. 460) is the authority for the statement that, in France, chorea is principally observed in the autumn and winter. My cases, arranged according to seasons, show the following order: Spring 152, summer 120, autumn 64, winter 101.

A comparison of the rheumatism tracing of this table with the varying states of the weather, leaving out the storm records, does not explain the reason of the highest point in April. That month shows the lowest mean relative humidity, and also the lowest barometer; but in opposition to this, the next highest month, viz., January, gives the highest mean relative humidity, and the highest barometer. The temperature in April averages a little over 50°, and January about 32°. The most changeable month is May, so that this cannot be the explanation.

It may be well to explain that the mean relative humidity does not show the *mean actual amount* of moisture contained in the air, but the *mean per cent.*. of the moisture that could be held in suspension at the *mean temperature* of each month; the amount representing complete saturation being indicated as 100.

Thus a given bulk of air at a low temperature, if saturated, and ready to drop its moisture, will become dry, if the temperature is raised, although it still holds the same amount of moisture.

This study may be considered as forging one more link in the obscure chain which binds together these two dissimilar affections.

Hospital Notes.

PENNSYLVANIA HOSPITAL.

Medical Clinic, Service of Dr. J. H. Hutchinson.

Secondary Syphilis.

The patient, aged 28, has always been a healthy man till two years ago, when he was exposed to the contagion of syphilis. Following this exposure he had a hard chancre, followed by constitutional symptoms, which have continued ever since. He was admitted to the hospital in general ill health, but having no suspicion of his condition; that is, not knowing he had any constitutional disease.

The whole surface of the body was covered with roseola; the face unfortunately has always been quite free from the eruption. I say unfortunately, because otherwise it might

have attracted attention and induced him to seek early treatment.

The character of this eruption simulates measles. It is slightly elevated above the surface, and varies in size from the head of a pin to a split pea.

The lymphatic glands throughout the body are enlarged, which is generally considered a sure evidence of the constitutional specific taint, and is a valuable diagnostic point.

Eruption is one of the first signs of constitutional syphilis, and generally makes its appearance about six weeks after exposure.

In this case there is some fever. The patient's temperature is 101°. Some authors dwell at length upon the specific fever, comparing secondary syphilis to the eruptive fevers, and tertiary symptoms to the sequelæ.

The treatment of secondary syphilis belongs to the physician, because it is constitutional, vigorous treatment. Here the bichloride of mercury in $\frac{1}{10}$-grain dose three times daily. Mercurial inunctions, pushed till the constitutional effects are produced, indicated by a slight touching of the gums.

In the second stage, iodide of potassium has little effect, and mercury a very good effect, but it must be continued for months, in some cases for a year, in some form or another.

On the other hand, for osteoscopic pains and rheumatic syphilis, as it is often called, potassium iodide should be substituted for mercury as the more appropriate treatment.

Under the above treatment, and suitable hygienic surroundings, the patient will undoubtedly show prompt improvement.

Medical Societies.

THE PHILADELPHIA NEUROLOGICAL SOCIETY.

Stated meeting, October 25, 1886.

The Vice-President, Charles K. Mills, M. D., in the chair.

Dr. Morris J. Lewis read a paper on

A Partial Study of the Seasonal Relations of Chorea and Rheumatism. (*See page* 710.)

Dr. Wharton Sinkler said that this paper was valuable and interesting, because it showed the close relation between chorea and rheumatism, which has been denied by some authors. For instance, Sturgis had 219 cases of Chorea in the Hospital for Sick Children in London, of which number 20 per cent. also had rheumatism; but he did not attach much importance to this connection, because, as he stated, fifteen per cent. of all children have rheumatism. Other writers have expressed the same views. This paper seemed to prove the relationship between the storm centres and attacks of rheumatism and chorea.

Dr. G. E. de Schweinitz reported

Eight Cases of Tobacco Amblyopia, One Complicated with Disease of the Spinal Cord.

Since 1854, when Mackenzie showed that defective vision might be produced by tobacco smoking, and since ten years later, when the subject was renewed and enlarged by the observations of Hutchinson, tobacco amblyopia has become one of the well-recognized facts of ophthalmological science. As is well known, progressive and usually equal failure of vision, unimproved by optical therapeutics; a feeling of wretchedness on the part of the patient; an ill-defined ophthalmoscopic picture; and a symmetrical oval scotoma in the fields of vision, lying between the fixing point and the blind spot, and often including both, in which the perception of green and red is especially defective, constitute the marked symptoms of this affection.

Case 1. A. G., æt. forty-nine, a bookkeeper, presented himself in the University Hospital, because his vision was failing and because of sleepless nights. He was a large, dark-haired man, with a restless, irritable disposition. Vision in the R. E. $\frac{20}{c}$, L. E. $\frac{20}{cL}$. Pupils about normal in size and reaction. Vision best in the early morning. Both optic nerves slightly hazy and gray in their deeper layers. The refraction H, but vision unimproved by the correcting glass. The fields of vision for white and red about normal. Between fixation—*i. e.*, the macula and the blind point, *i. e.*, the optic nerve entrance—there was an oval, slightly sloping, relative scotoma, including both. In this area green appeared dirty white, and red could not be distinguished as such. For twenty years he had smoked excessively, averaging two pounds of Cavendish a month. He drank one pint of spirits a day. He was ordered to stop tobacco absolutely, and to diminish his daily quantity of spirits. In a month his vision had improved to $\frac{20}{XXX}$ in each eye, and with his correcting glass he could read with fair ability.

Case 2. B. E., æt. fifty-three, laborer, came to the University Hospital for failing vision. He was a small, dark-skinned man, with fairly steady nerves. Vision, R. E. $\frac{20}{LXXX}$,

L. E. $\frac{20}{L}$. Pupils normal in size and reaction. Vision worse in a bright light. Both optic nerves were gray-red, and the veins full and dark. The fields of vision showed no marked peripheral change, but perfectly characteristic oval scotomata were present. This man had smoked two pounds of "hard tobacco" a month for many years, and was accustomed to drink one quart of spirits a week. The usual order to stop tobacco was given. Sufficient time has not yet elapsed to prophesy how successful the case will be.

Case 3. J. M., æt. thirty-five, a mechanic, came to the University Hospital because of defective vision, headache, and great nervousness. He was a short, thick-set man, tremulous and despondent. Pupils exhibited no abnormalities. Vision, R. E. $\frac{20}{LXXX}$, L. E. $\frac{20}{C}$. The nasal edges of the optic nerves were hazy and the temporal sides gray; arteries rather small. The fields for white and red not far from normal, those for red, being slightly contracted. In the right eye from fixation, and including it, and passing outward, there was an oval scotoma for red, and green which reached to the blind spot, but did not embrace it. In the left eye a similar rather more irregular scotoma. Up and out from the fixing point a small area of the scotoma was absolute. This man for fifteen years had smoked about six ounces of coarse tobacco a week, and occasionally cigars and cigarettes. He denied taking anything to drink, except a little beer or ale. In eight days his vison in right eye had become $\frac{20}{XXX}$, and in the left eye $\frac{20}{L}$. He then passed from observation.

Case 4. Ida J., æt. twenty-seven, came to the University Hospital because of failing vision and great "nervousness." She was a finely-formed brunette, of rather pallid countenance aad excitable temperament. Vision in R. E. all of $\frac{20}{XL}$ some of $\frac{20}{XXX}$. The L. E. had been removed years ago for disease. Pupil responded freely to the change of light and shade, and was about medium size. The optic nerve was pallid, edges clear, arteries rather small. The field of vision, both for white and red, was somewhat contracted and surrounding fixation in a band-like manner, but not extending to either side, there was a relative scotoma in which this color appeared "brownish," or rather "dull colored." The girl used no tobacco, but had worked for some years in a tobacco factory. On this account she was advised to get other employment, and also to take one twenty-fourth of a grain of sulphate of strychnia three times a day. In two weeks the scotoma was no longer demonstrable, and in about one month the vision had returned to normal and is now above normal.

Case 5. H. H., æt. fifty-eight, a shoemaker, came to the Dispensary of the University Hospital because his eyesight was so poor he could no longer see to do his work. He was a medium-sized man, with dark hair beginning to turn gray, tremulous and easily startled. Vision in the R. E. $\frac{20}{C\ C}$, the same in the L. E. The pupils were small, and failed to respond to the changes of light and shade, although they contracted in the efforts of accommodation. The optic nerves showed a large shallow excavation, widening of the scleral ring all around, and were of a distinctly gray color. There were no changes in the central circulation. The fields of vision showed slight contraction for white, distinct limitation for colors, and oval sarcomata from fixation to blind spot, including both. The man smoked three ounces of tobacco weekly, and drank whisky, but not to excess. Further examination developed the fact that the patellar reflexes were absent, that with closed eyes the upright position was maintained with difficulty, and on attempting to walk the gait became staggering, if not positively ataxic, and that preceding the time of failing vision there was a history of diplopia. These symptoms, together with the state of the pupils, rendered the presence of sclerosis in the posterior columns of the cord a fair inference. There was no history of syphilis. Examination of the urine revealed it normal. The patient was ordered to stop the use of tobacco and take iodide of potassium. Although two months have elapsed since he applied for treatment, no improvement in his vision has taken place, nor have the scotomata changed or lessened.

Case 6. W. H., æt. fifty-eight, a farmer, applied for treatment in the University Hospital because of a "cloud" before his vision and inability to do even ordinary coarse eyework. He was a well-preserved, large-framed man, with iron-gray hair, and presented no noteworthy unsteadiness of the nervous system. Vision in the R. E. counts fingers at two feet, in the L. E. $\frac{10}{C\ C}$. The pupils were small, they responded to the changes of light and shade, and also to the efforts of accommodation. Both optic nerves were small, surrounded by a halo, and their edges and the surrounding retina hazy. The disks were gray-red in color. In the neighborhood of each macula were slight patches

of choroiditis. In the R. E. the field of vision for white was contracted, but not markedly so, and the fields for blue and red showed similar slight limitations. Between fixation and the blind spot, a large irregular scotoma for all colors. In the area surrounding the fixation, and for a small distance toward the blind spot, the loss of color was absolute, from there to blind spot relative. In the L. E. the field for white was limited above, and the fields for red and blue irregular and constricted. A similar scotoma, absolute near its centre, extended between fixation and blind spot, and included both. This man smoked four to six cigars daily, and drank "an occasional glass of whisky." The patellar reflexes were prompt, and greater on the right than the left side. His urine has as yet not been examined.

Cases 7 and 8. These cases occurred in private practice, and were both men over forty years of age, of active business habits, who complained of indistinct vision. In both the vision was not far from normal, viz, $\frac{15}{XX}$, and in both the eye-grounds presented no abnormal feature. There were no true scotomata, only slight dimness of the perception of green and red between the macula and the optic nerve. These men were inveterate smokers. The difficulty of vision disappeared in one patient when he ceased using tobacco; the other declined to abandon his habit. While tobacco was evidently producing deleterious effects, these cases can scarcely be classified as true instances of tobacco amblyopia.

In three of the cases reported, the ophthalmoscopic examination revealed "hazy disks" either with or without full, dark retinal veins (cases 1, 2, and 3); in two, if the last record be included in the list, there were no fundus changes (cases 7 and 8). In one the optic nerve was pallid, the arteries rather small, perhaps the appearance of beginning atrophy (case 4), and in one the nerve showed evidences of gray atrophy (case 5), while in another the appearances were those of a subsiding neuritis (case 6). Three of these cases are perfectly typical instances of tobacco amblyopia (cases 1, 2, and 3); and two of them, if not characteristic cases, at least showed the results of tobacco impression (cases 7 and 8). Case 4 is an atypical one, inasmuch as the scotoma surrounded the fixation, but did not include it or pass to either side; and, furthermore, is noteworthy because of the fact that the tobacco found its entrance into the system by absorption through the skin. This woman worked in tobacco, but did not use it. Case 5 may be one of those rare instances in which a central scotoma appears with a spinal atrophy of the optic nerve; but inasmuch as the man used tobacco, although moderately, its influence cannot be excluded. An almost precisely similar case is recorded by Gowers (*Med. Ophthalmoscopy*, p. 111). In case 4 it is doubtful if the use of tobacco produced the scotoma although, as in the last instance, the patient was accustomed to its use, and hence its influence cannot be excluded. The whole subject of tobacco amblyopia has so often and so thoroughly been discussed, notably by Mr. Nettleship (*St. Thomas's Hospital Reports*, 1878), that it is useless to do more than report these cases and point out the features that are interesting.

Dr. B. Alex. Randall remarked that some ophthalmologists disbelieve in the existence of tobacco amblyopia. Very few cases have been put on record in which the influence of alcohol could be wholly excluded; but the combination of alcohol and tobacco is certainly a serious disturbing element in a number of cases. This affection is constantly coming under notice—occurring some eight or ten times in a thousand cases. While the scotoma is usually of an oval form, he had seen it distinctly angular (as in case 4) in a case typical in other respects.

It has recently been claimed that the absolute quantity of nicotine used does not bear that relation to amblyopia that we should infer, and that those who smoke the finest cigars are more liable to this affection than those who smoke the poorest and strongest.

Dr. Jas. Hendrie Lloyd asked if this affection were due to neuritis or to some disturbance of the intra-ocular circulation? The cases reported suggested an interesting analogy between tobacco amblyopia and peripheral neuritis, especially that form due to toxic agents. Is this a form of toxic neuritis of a special nerve?

Dr. J. Madison Taylor, referring to one of the cases reported, asked if it were not possible to have a powerful effect from the absorption of tobacco by the skin and lungs? In children working or living in tobacco shops, he had, in several instances, seen profound disturbance of the heart as the result of absorption.

Dr. Louis J. Lautenbach remarked that there had always been an element of doubt about these cases, and that of late this had become stronger. There are cases reported in which alcohol has been stopped, while the tobacco has been continued, and the patients have gotten well. Dr. Minor, of Memphis,

reports eight such cases. In addition to the discontinuance of alcohol, he administered in these cases either iodide of potassium or strychnia. Nettleship, Foerster, and a few others, have succeeded in curing some of these amblyopia cases by the discontinuance of tobacco alone. About two years ago, at the Philadelphia Eye and Ear Dispensary, he had experimented in this matter, and had cured a number of cases by removing alcohol, allowing them to use tobacco, without the use of any medicines. The same treatment had resulted satisfactorily in two cases treated in private practice. One case was that of a professional base-ball player, who was in the habit of drinking thirty-five or more glasses of whisky, and smoking from eighteen to twenty-five cigars a day. When examined, both eyes gave V.=$\frac{3}{LX}$? The patient was directed to stop the use of strong liquors, but to keep on with his tobacco. In four days later V.=$\frac{3}{XXXV}$. Vision continued to improve, although no medicines were used.

The condition which causes this amblyopia may be a slight grade of retro-ocular neuritis, involving only the macula lutea fibres, which may be induced not only by tobacco but also by alcohol; lead occasioning it in some few cases. Depressed conditions of the system may probably cause it. This amblyopia with central scotoma is coming to be looked upon not as a special symptom of tobacco abuse, but rather as an indication of the depression of the general system, which may be brought about by various poisons.

Dr. Wharton Sinkler referred to a paper published in one of the New York journals by Drs. Roosa and Ely, giving the results of the examination of a large number of workers in cigar factories, many of those examined smoking a great deal. Only a very small proportion of these cases was found to present any defect of vision or any disorder of the nerve. He asked if in the experience of other members they had found that a large proportion of nervous diseases were attributed to tobacco? He saw but few patients at his clinic at the Infirmary for Nervous Diseases with nervous disorders which could be directly attributed to the use of tobacco.

A point to be remembered in the consideration of this subject is that a person who takes alcohol will use more tobacco than one who does not. If he stops his alcohol he will take less tobacco.

Dr. Morris J. Lewis stated that in studying the subject of writer's cramp, he had found that in the majority of cases the use of tobacco increased the difficulty. A few out of forty-three cases said that it did no harm, and three said that it was of service.

Dr. Francis X. Dercum asked if those who used tea or coffee to excess, especially tea-tasters, presented symptoms analogous to those presumably caused by tobacco and alcohol?

Dr. B. Alex. Randall said that there were some cases in which alcohol *could* be entirely excluded in the causation of this affection. As to the pathology of the trouble, it is interesting to note that he knew of no case on record of true neuritis in the sense of anything like a choked disk, which had any apparent relation to tobacco abuse; although such cases are not rare in lead poisoning and other toxæmic conditions. In all cases of actual neuritis of the optic nerve, as inflammation of other nerves, strychnia has to be carefully avoided in the acute stage. In most cases reported the use of strychnia had no injurious effect, and in fact caused, or was followed by, improvement. In some cases where strychnia has been given and the alcohol and tobacco both continued, recovery has taken place. The amount of poison required to produce a certain effect probably depends upon the constitution and condition of the patient. If the general condition is brought up, a given amount of the poison no longer has the same effect.

Dr. Charles K. Mills, referring to the question of Dr. Sinkler, stated that his experience agreed with that of Dr. Sinkler, that nervous disorders are rarely attributable to the use of tobacco, although some cases of tremor and general nervousness, and a few other affections, undoubtedly originate in this way.

Dr. George E. de Schweinitz, in closing the discussion, said that he believed that in these cases there was an axial neuritis. He has had no experience with the poisonous effects of tea and coffee. Some of the cases reported had recovered, although the free use of spirits had continued. One of the patients continues to drink a pint of whisky a day, and yet his vision has remained normal since the discontinuance of tobacco. The only way to reach a satisfactory explanation of this subject is to continue the experiments.

One object in presenting this series of cases was to call attention to the importance of a careful study of the field in nervous cases. If this were done more frequently, many interesting discoveries would probably be made.

Referring to the question of Dr. Taylor,

he said that tobacco is freely absorbed through the skin, but inasmuch as it is rare to find scotoma under such circumstances, he reported the case.

Dr. Francis Dercum reported

A Case of Unusual Paresis of the Forearms.

Dr. Charles K. Mills referred to three cases which had been reported a few years ago by Dr. Kerlin and himself. These cases were studied at the School for Feeble-minded Children at Elwyn. The patients were brothers, and in them was a marked combination of pseudo-hypertrophy and muscular atrophy. One of the boys, who has since died, presented in the calves the typical appearance of pseudo-hypertrophy, and also in one or two other isolated portions of the body. In the back, however, were all the distinctive signs of progressive muscular atrophy. In the second case the changes were principally those of progressive muscular atrophy. In the third there was a combination of the two conditions. Why in one case we get the pseudo-hypertrophic form, and in another the atrophic form, he was not prepared to say. He believed that in all cases there are cord and nerve lesions, but he did not know which of these was primary. In the treatment of such cases, that pursued in the present instance would seem to offer the most hope. He was in the habit of putting these cases on strychnia, iron, cod-liver oil, and similar tonic and nutrient remedies. He had never seen much benefit from local treatment, but if myositis was present he thought it worthy of a trial.

Dr. James Hendrie Lloyd said, with reference to the age at which this affection may develop, that he had recently seen a case in which a married woman, thirty years of age, who had been under treatment on several occasions without a positive diagnosis having been made, returned after an interval of four months with hypertrophy of the muscles of the calf, lordosis, and other characteristics of pseudo-muscular hypertrophy. This was the first case which he had seen in which the disease had apparently occurred as a primary disease in an adult with no hereditary tendency.

Dr. William Osler remarked that some observations had been made by an English physician with reference to the atrophy which follows great use of the muscles. After examining the microscopic specimens, he agreed with Dr. Dercum in regard to the condition present in this case. There was no essential difference between the atrophic and the pseudo-hypertrophic form of the disease, and both may be present in the same case.

Dr. William Osler exhibited the following specimens:

Pachymeningitis.

J. K., was admitted to the drunkards' ward of the Philadelphia Hospital, on August 26th, with delirium tremens, and died September 4th. I did not see him during life, but from the account given by the resident physician, he appears to have had an ordinary attack of delirium tremens, without any paralysis, local or general. He was not in a condition to give a satisfactory account of himself. Death took place from exhaustion. The post-mortem showed an extensive pachymeningitis of the right half of the dura mater. The specimen presents layers of exudation two lines in thickness over the central portion of the dura, gradually becoming thinner towards the tentorium or the orbital surface. In these regions there was a delicate uniform sheeting on the dura mater and no hemorrhage had as yet taken place; but on examination with a low-power lens there could readily be seen a plexus of wide vessels. In the central part there were several layers of altered blood, alternating with colorless firmer exudation. The surface of the pia mater of this hemisphere was a little stained, but there had evidently not been any pressure upon the convolutions. There were no other lesions.

Phthisis; Tubercular Meningitis; Aphasia.

J. McD., æt. thirty-six, laborer, was admitted to the Philadelphia Hospital, June 5th, with phthisis. There was nothing special in his family history; five of his brothers and sisters had died from causes unknown to him. He had been ill for over eighteen months with cough, fever, chills, and sweats. Had brought up blood, and had had severe diarrhœa. When I saw him first, on September 4, there were signs of extensive disease in both lungs. Ten days before he had two convulsions, after which he had some difficulty in talking, On the 4th he looked bright and intelligent, the pupils were dilated, and there was no paralysis. Expressed himself with difficulty; when asked his name, said *Joseph Mac*, but could not say the *Donald*. After several attempts and a good deal of worry, he did so, and seemed much pleased. Some words he said clearly, others he could not. Thus he could read the letters of the word *shaken*, but could not pronounce it. He was delirious at times during the next two weeks, and one night he got from the ward on the fire-escape. The aphasic condition improved somewhat. The eye-grounds were examined twice, with neg-

ative results. At the time of my visit on September 10, he had an epileptic seizure, strong spasm of respiratory muscles, and great lividity. Tonic spasms of arms, gradually relaxing and becoming choreic. Facial muscles in violent action; face drawn to the left, eyes to the right (strongly) and upward. He became unconscious the next day, and died on the 14th. The autopsy showed extensive disease of the lungs. The brain was large; at the base the membrane was thickened and infiltrated, and tubercles existed along the vessels. On exposing the Sylvian fissures, the pia on the left side covering the insula was very thick, and studded with tubercles the size of a pin's head. The process was most advanced upon the three or four posterior gyri of the insula. The gray matter was reddened and soft. The third left frontal convolution was not specially involved; there were a few isolated tubercles on the pia, but the membrane was not thickened. In the right Sylvian fissure there were tubercles scattered along the vessels, and the arteries of the anterior perforated spaces presented many bead-like and oval swellings. The ventricles were dilated, and their walls softened.

Embolism of Right Middle Cerebral Artery; Chronic Nephritis.

J. W., laborer, aged forty-nine, was admitted to the Philadelphia Hospital, October 7, 1886. No special history could be obtained, as he was very dull and heavy. When I saw him on the 9th he was apathetic, answered questions with difficulty. The face was anæmic, and he had a decidedly renal look. The pulse was slow and hard, sixty to the minute. No increased heart dullness, possibly a murmur at apex, but it was not at all distinct, and at base very ringing. There were albumen and casts—hyaline. The case was regarded as one of chronic interstitial nephritis.

On the morning of the 12th he had a hemiplegic attack. I found him at 1 o'clock p. m., comatose, with puffing respiration and complete left hemiplegia, including face. Right pupil larger than the left. He died during the night.

The autopsy showed cirrhotic kidneys, slight atheroma in large vessels, moderate hypertrophy of left ventricle. The mitral valve presented recent vegetations, three in number, on the auricular face of segments, freely movable, and on the posterior flap, a flattened area looking as if eroded. The right hemisphere of the brain looked fuller than the left, and the vessels were not so full, particularly in the central region. The vessels of the circle of Willis were denuded *in situ*, and the right middle cerebral just beyond the first two branches (temporal) was found plugged with the firm embolism here shown. It was very evident before opening the vessel, as it showed grayish-white throughout the coat, while on either side of it were dark clots, and the branches beyond it were very small. The embolus was firmly adherent, and had a small pale clot on its proximal, and a firm dark one on its distal side. Examination showed it to be an endocardial vegetation, and it doubtless came from the rough spot on the posterior segment. The convolutions of the central portions of the hemisphere were swollen and œdematous, particularly the gray matter, and softer. There was a light gray yellow tint, but there had not been time for much change. The right anterior cerebral was greatly enlarged, three times as big as the left, doubtless a compensatory process.

Dr. Charles K. Mills remarked that cases of pachymeningitis hemorrhagica were somewhat common in the Philadelphia Hospital. He had met with a comparatively large number of cases in making autopsies in that institution. A form of hemiplegia met with in the wards of this hospital, is undoubtedly due to pachymeningitis hemorrhagica. These cases make partial recoveries, and then again break down, and at the autopsy is found the condition exhibited to-night. He had reported one case five years ago, with a number of other cases, in the English journal *Brain*. This condition is sometimes mistaken for embolism, hemorrhage, or some other form of disease producing hemiplegia.

In some of the cases he had seen, there had been distinct naked-eye flattening of the convolutions of the motor region, which he supposed accounted for this peculiar, variable form of hemiplegia.

Adjourned.

The Sanitary Condition of Florence.

Information has been received from the Italian Consul-General to the effect that the Syndic of Florence states that, owing to the precautions adopted for the preservation of health, the sanitary condition of that city and its environs is excellent, there having been, during the months of June, July, and August, a notable diminution of deaths both from common maladies and also from those which especially manifest themselves during the hot season.

EDITORIAL DEPARTMENT.

PERISCOPE.

Solanine—a Substitute for Morphine.

The *Medical Record*, November 20, says: The many disadvantages of opium and its alkaloids are too well known to require mention, and while they are not sufficient to counterbalance the good effects of these drugs, they are of enough importance to make an equally efficacious and more innocuous substitute a desideratum. According to Dr. Geneuil (*Bulletin Général de Thérapeutique*, September 30, 1886), we have such a substitute in solanine, which is not a newly-discovered remedy, but rather one which has fallen, the author thinks, into unmerited disuse.

Solanine was discovered by Defosses in 1821, in the berries of the nightshade (*Solanum nigrum*), and has since been found by others in the stems, leaves, and berries of the bittersweet (*S. dulcamara*), and other varieties of solanaceæ. It is now prepared from potatoes, by boiling the young shoots in water slightly acidulated with sulphuric acid, and adding ammonia to the warm decoction. It can also be obtained from the parings of very young or very old potatoes. The alkaloid crystallizes in fine silky needles, insoluble in water, and but slightly soluble in ether, oils, and cold alcohol, but dissolving more readily in hot alcohol. It has an acrid taste, and imparts a burning sensation when placed in contact with the mucous membrane of the mouth.

This substance was first employed in medicine by Julius Clarus, of Leipzig, who published a memoir on the subject in 1859. The remedy, however, was never used by others to any extent, possibly because given in insufficient doses. Clarus gave it in doses of from one-tenth to three-fourths of a grain, whereas Geneuil states that it has no appreciable effect unless given in doses of from one to five grains per diem. It may be administered in pill, or the hydrochlorate, which is very soluble in distilled water, may be employed subcutaneously in single doses of about one-half grain, repeated three or four times a day.

The author has tried solanine in a number of cases of neuralgia, rheumatism, obstinate vomiting, spasmodic nervous affections, asthma, and bronchitis, and from the results obtained is led to believe that the remedy will prove to be of the greatest value in the treatment of these and similar affections. The following are the conclusions of his paper:

1. Solanine is a poison to the terminal motor plates. It narcotizes the medulla and spinal cord, causing a paralysis of the terminal, sensory, and motor nerves. By reason of this action solanine is to be classed among the best of the analgesics.

2. The drug may be prescribed in large doses without danger, and presents none of the inconveniences of morphine or atropine. There is no danger of cumulative action.

3. Solanine does not cause congestion of the brain, even in the aged, and, probably, a like freedom from this danger exists in the case of children.

4. In all cases where it is necessary to calm excitement, relieve pain, or overcome spasm, solanine promises excellent results. It may be given with advantage in the place of morphine for the relief of any of these conditions.

If the author's exalted opinion of this remedy is borne out by further experience, it will indeed prove to be one of the most valuable of recent additions to the materia medica. But medicine is an uncertain science, and others may not meet with such wonderful success as Dr. Geneuil himself has had.

The Equine Origin of Tetanus.

The *N. Y. Med. Jour.* (Oct. 30) says that a practitioner of Libourne, in France, who states that tetanus is rare in that locality, has written M. Verneuil a letter, in which he says that he has observed three cases of the disease there, one of which was that of a dragoon who wounded his foot in a chase after a runaway horse, and another that of a man whose injury was produced by the bite of a horse. The letter is published in the *Gazette Hebdomadaire de Médecine et de Chirurgie*, the same journal in which, as our readers are aware, M. Verneuil lately broached his theory of the equine origin of tetanus.

On the other hand, in a subsequent issue of the same journal, M. Saint-Vel adduces a number of facts that are hard to reconcile with M. Verneuil's theory, or at least with the assumption that it holds good invariably. The writer first alludes to his own observa-

tions in early life, when, living in a region where tetanus was much more prevalent in man than in the horse, he knew of a number of cases. He then calls attention to the frequency of tetanus in Oceanica, although on many of the islands the horse is unknown, and recalls the case of the frigate Pearl, which anchored in the Bay of Carlisle, Island of Santa Cruz, on the 12th of August, 1875. Those of the ship's company who landed were received by the natives with arrow-shots, and the commodore and five men were wounded. None of the wounds were serious in themselves, but the medical officer, bearing in mind the frequency of tetanus in the tropics, advised the commodore to try to make Australia. On the 17th, the northern point of New Caledonia being abeam, the commodore was attacked with tetanus, and died on the 20th. Two young seamen also died, one on the 18th and the other on the 21st—both of tetanus. Another case was that of a young sailor who injured his foot while handling a cannon on shipboard in the roadstead of Ajaccio, and was attacked with tetanus on the twenty-second day. Finally, after the French attack on the forts of Petropaulowski, four cases of tetanus showed themselves among the wouned—three on one vessel and one on another.

Our readers will remember that M. Verneuil alluded incidentally to the rarity of tetanus at sea in support of his theory of the origin of the disease from the horse. But, even if we grant that, in general, its occurrence on shipboard is unusual, it must be admitted that a single instance will suffice to set the equine theory aside in that particular case, unless we fall back on another of M. Verneuil's suggestions—that the period of incubation may be extremely prolonged. However, stretch the possibilities in this direction as we may, the supposition that all three of the victims on board the Pearl, who died within the space of three days, after recent wounds received at the same time, succumbed to a disease acquired from the horse before the vessel left home, becomes so improbable as to border on the absurd. It must be said, therefore, that the naval observations adduced by M. Saint-Vel go far toward vitiating what little there was of a convincing character in M. Verneuil's presentation of his views.

Anæsthetic Effect of Ointments.

The *Lancet* says that Dr. Toporoff has published in the *Russkaya Meditsina* an account of a series of observations made with the object of determining the absolute and relative effects of various narcotic and anodyne ointments on the sensitiveness of the skin, with reference both to mechanical and electrical excitants. The portion of the surface to be experimented on was first cleansed and moistened, and the sensibility estimated by means of a Weber's compass æsthesiometer with tortoise-shell points, the direction of the line joining these being vertical, as it is known that sensibility as tested by the compass is greater in a vertical than in a horizontal direction. When the least distance at which two points could be distinguished was determined, a drachm of the ointment was rubbed into the surface over a circular area measuring an inch and a half in diameter for ten minutes. After the lapse of another ten minutes the sensibility was again estimated, and a third time after an interval of half an hour from the end of the rubbing. The electrical sensibility was tested by means of the primary current of a Spamer's induction apparatus, the secondary coil being gradually pushed over the primary, so as to increase the strength of the current according to the divisions of a scale. With a 1-to-8 belladonna ointment the tactile sensibility was always diminished, the mean difference being 0.6 centim. at ten minutes and 1.1 centim. at thirty minutes. When lanoline was used as a basis instead of lard, the mean diminution was only 0.55 centim. at ten minutes and 0.95 centim. at thirty minutes. With hyoscyamus, aconite, and conium, much the same results were obtained, but the degree of anæsthesia produced was slighter. With chloroform ointment of the same strength (*i. e.*, 1 to 8), the diminution was 0.66 centim. at ten minutes and 0.8 centim. at thirty minutes. In this case the substitution of lanoline for lard in the composition of the ointment produced a markedly diminished effect, the mean figures being 0.3 centim. at ten minutes, and 0.62 centim. at thirty minutes. Turning now to ointments made of powdered substances, it was found that, so far from any anæsthesia being produced, the sensibility was actually increased by them. This was the case in almost all the observations made with hydrochlorate of morphia ointment (1 to 60), opium ointment (1 to 19), and bromide of potassium ointment (1 to 6), the augmentation being less when lanoline was employed than when the ointments were prepared with lard. No very decisive results were obtained by the observations of the effect of narcotic ointments on electrical sensibility, but the author instituted a series of observations in order to

determine the influence of the friction with lard and lanoline alone, and found that ordinary sensibility was invariably increased, for a short time at least, the mean figures being, for lard, 4.25 centim. at ten minutes, and 1.75 centim. at thirty minutes. In the case of lanoline, the mean increase at ten minutes was 5.5 centim., but no effect at all was detected at thirty minutes. The author remarks that the hyperæsthesia apparently produced by the ointments prepared with powdered narcotic substances — morphia, opium, and bromide of potassium—is therefore probably due to the mere friction with the lard, the medicament being unable in the form of powder to penetrate through the skin. According to these researches, lanoline would appear to be a less advantageous basis for anodyne ointments than ordinary lard, the difference in favor of the latter being especially marked in the case of chloroform ointment. The effect of the ointments seemed also to vary considerably with the region of the body experimented on. Thus, while the diminution produced by chloroform ointment on the forehead is stated as .95 centim., the figure indicating its effect on the inner surface of the thigh is only 0.1 centim.

Ergotism in Cows.

Some discussion has been taking place lately with regard to ergoted grasses producing abortion in cows, and the question does not yet appear to be answered as to whether and to what extent the accident is due to the Claviceps purpurea, which in some seasons is a very common parasite on the herbage of pastures. By some authorities it is believed that ergot is the cause of the widespread epizoötics of abortion which are sometimes reported as occurring among cattle, and which cause heavy loss to stock-breeders. By others this effect of ergot is doubted, and these doubts would appear to be justified by very conclusive evidence of an experimental kind. It has been given in large and repeated doses to cows, bitches, cats, swine, and rabbits, in all stages of pregnancy, but its ecbolic action has not been observed in them, and the conclusion arrived at was that amongst the lower animals ergot, whether given by the mouth or rectum, in single large doses or for some time continuously, has no tendency to expel the contents of the uterus at any period of gestation. Abortion in cattle is undoubtedly due to many causes. When sporadic, it may follow injury or disease; but when it occurs in a herd of pregnant cows, all or nearly all aborting after the first case, then the occurrence looks mysterious, and is popularly believed to be owing to "sympathy" among the cows, a kind of imitative action brought about by the animals' imagination. This notion has, of course, no foundation in fact, and multiple cases of abortion can be truthfully accounted for by infection conveyed from one cow which has aborted to others which are in calf. Veterinary surgeons had long, from observation, come to the conclusion that septic infection, possibly through the genital organs, was the principal if not the sole cause; and some years ago Franck, of the Munich Veterinary School, made some interesting experiments on pregnant cows, which demonstrated that abortion could readily be brought about by introducing a very small quantity of matter obtained from the vagina or after-birth of a cow that had slipped its calf into the vagina of a pregnant one. This matter was found, on examination, to teem with micrococci. In order to prevent outbreaks of abortion, viewing it as an infectious disease, cattle-breeders should be thoroughly aware of the premonitory signs, which are usually well marked, and at once separate the animal which shows them from his fellows. When the accident has happened in a cowshed, then measures of a sanitary kind should be speedily adopted, as if dealing with a most infectious malady. By acting in this way, the heavy losses which are so frequently reported as the sequel of "warping" would be no longer heard of.

The Treatment of Diphtheria.

Dr. James Merces thus writes in the *Lancet*, October 30:

During the past twelve months it has been my share to treat no less than thirteen cases of diphtheria, with one death. No originality is claimed in the plan adopted by me, though it may somewhat startle a few at the large and frequent doses of certain drugs ordered. Briefly, my cases were treated, with the exception of very young children,

1. By internal treatment.
2. By emetics.
3. By gargles.
4. Hygienically.

1. Where the depression is marked, though there may only be the slightest indication of a certain questionable gray slough, with a moderate amount of elevation of temperature and glandular enlargement, a mixture (preceded by a gentle aperient) of the following should be ordered: Solution of per-

chloride of iron, six drachms; dilute nitric acid, two drachms; glycerine, one ounce; water to six ounces; an ounce to be taken every two hours. After the lapse of a few hours patches may be noticed extending in certain directions, while the original patch or patches will appear somewhat shrivelled, the temperature and glandular enlargements probably increasing.

2. An emetic may now be used. Apomorphia acts in these cases most satisfactorily, from three to five minims promptly producing emesis in from one to three minutes. If now the ejected contents be examined, portions of slough may be detected. The patient, though rather prostrate, will be much relieved of urgent dyspnœa. It is rarely necessary to repeat the apomorphia. The iron mixture is to be continued every second hour.

3. If the patient be intelligent and able to use a gargle, the following will be found most beneficial, establishing a healthy condition to the surface from those portions of the fauces and tonsils where the patches have been recently bared of membrane in the efforts of sickness produced by the apomorphia. The gargle should be made in this fashion: In a six-ounce bottle place a drachm of chlorate of potash, add to it half a drachm of pure hydrochloric acid, and while the nascent chlorine gas is being generated fill the bottle with water, and direct that an ounce of the gargle should be used (the head being well thrown back) every third hour.

4. The patient's strength should be maintained by small and frequent quantities of milk and clear beef-tea unflavored with pepper, salt, etc. Alcohol is urgently demanded. and may be given with a free hand and with much benefit should prostration be marked. It is absolutely imperative that the temperature should be uniform—say 70° F., with a current of fresh air.

Twin Labor Complicated with Rupture of Large Varicosed Labial Veins.

Dr. Ambrose Atkinson thus writes in the *Lancet:*

Some little time ago I attended Mrs. F——, aged thirty-nine, in her eighth confinement. Labor commenced about 8 p. m., though she had been poorly for over twenty-four hours. On examination, a breech presentation was made out. After waiting some little time it came well down into the pelvis, and when near the outlet the right labium began to swell. The delivery was easy, but whilst separation was being effected, the patient was seized with another very strong pain. On examination, made with difficulty, a second group of membranes could be felt, which I ruptured, and the patient obtained ease. This procedure, however, did not affect the tumor, which steadily increased to an alarming size. Another pain coming on, the tumor suddenly burst on its inner side, deluging the bed, etc. Not caring to take the whole responsibility of the case, I sent for Mr. Holmes, of Burmantofts, requesting him to bring the forceps, with the hope of seizing the presenting head. In the meantime, as hemorrhage was freely going on, I made a firm pad of a napkin, and held it to the parts, so as to effectually stop the bleeding. On Mr. Holmes's arrival, he slipped the short forceps on to the second head, when the child was suddenly expelled, the injured part being at the same time firmly compressed. The placentæ were then easily disposed of. On examining the damage, it was found that the inner side of the labium was so torn that four fingers could be passed into the opening, which led to a cavity sufficiently large to hold the whole hand. The bleeding had now abated, so the cavity was filled with strips of lint well dusted with iodoform. Pressure being applied by means of a firm spica, the patient was left for the night. On the following morning opium was administered, and the plugs were removed, very little bleeding occurring. The vagina was syringed out with perchloride solution (1 in 3000), and an iodoform suppository placed well up into it; the wound was then dusted with iodoform. This was done twice a day for a week, the patient making a very good recovery. A piece of vein about three-quarters of an inch long, which lay across the wound, sloughed off about the fifth day, a little bleeding taking place. On questioning the patient about the vein, she told me after all was over that she had had a lump there for some time, which got larger towards night, but she did not think it worth noticing. The question is, supposing I had known about it before delivery, could anything have been done to save rupture?

Optic Neuritis in Head Injuries.

Before the Ophthalmological Society of the United Kingdom (October 21), Messrs. Walter Edmunds and J. B. Lawford read a communication based on twenty-four cases of head-injury, in which the condition of the optic nerves had been observed either ophthalmoscopically or microscopically. The cases were divided into three groups:

1. Cases which ended fatally directly, from the severity of the head-injury; 11 cases, 4 of which had optic neuritis, were included in this group.

2. Cases which ended fatally, indirectly from complications; this group comprised 4 cases, 2 of which had optic neuritis.

3. Cases which recovered; 8 cases, 6 of which had optic neuritis, were included in this group.

As to the cause of the optic neuritis, it was attributed to spread of inflammation from the seat of injury to the optic nerves; this might take place either along nerve-tissue or by the meninges. The authors adopted the latter view, because:

1. While in some of the cases in which there was optic neuritis, basal meningitis was found, it never occurred in those cases in which optic neuritis was absent.

2. Those cases in which the base of the skull or brain was injured, generally had optic neuritis, while those in which the injury was confined to the convexity of brain, such as punctured wounds, had not.

3. In some cases of neuritis, transverse sections of the optic nerve showed the inflammation most marked at the periphery of the nerves, and in the sheath space.

Dr. Brailey, referring to the microscopical drawings that were exhibited, said that it was evident that there were two distinct classes of cases, and his own experience quite confirmed this—one in which there was considerable effusion between the pial and dural sheath, and the other in which the bulk of the inflammation was found in the intertrabecular tissue. How were these differences to be accounthd for?

Mr. Silcock, referring to the case of injury to the vertex where there was no optic neuritis, asked whether there was any meningitis at the base or vertex.

Mr. Edmunds replied that in that case there was meningitis of the vertex, but not of the base. In reply to Dr. Brailey, he pointed out that the drawings represented very different stages of the affection, that where the effusion took place outside the pial sheath was from a case that proved rapidly fatal in a few hours, the other represented the appearances when death took place some days later. He believed that would fully account for the apparent differences.

The Toxical Effect of Tartar Emetic.

Dr. A. H. Langston thus writes in the *Nashville Jour. Med. and Surg.:*

Allow me to give a report of the toxical effect of tartar emetic (*antimonii et potassæ tartras*) in a smaller quantity than I have ever noticed reported from any authority. I wish to do this for the purpose of directing the attention of others, and especially that of the young and inexperienced, to the importance and safety of observing great caution in the administration of this common, useful, but potent, article of the materia medica, and also to warn them against relying with too much confidence on statistical reports in reference to it as a poison, and to impress them with the necessity of considering probable idiosyncracies or constitutional susceptibility to its power before venturing any dangerous risks in prescribing it.

Mrs. Rebecca D——, of a strumous habit, was confined on August 19, 1886, with her first child. In a few days after delivery both breasts became inflamed, which threatened to run into deep-seated abscess. Knowing her scrofulous taint, I was very solicitous to avoid this result, and in order to forestall the formation of matter, besides every local agency usually employed, ordered gr. ss. tartar emetic in solution, with directions, in case it did not produce nausea, to repeat in two hours, with double the dose. In less than an hour afterward I was summoned to her in haste, and found her greatly prostrated, vomiting every few minutes, bathed in a profuse sweat, with cramps in her stomach and bowels, weak and rapid pulse—all indicating a mild case of poisoning by only one-half grain of this medicinal agent, which has never been considered by toxicologists as a poison of any specially active power. I feel sure that half a grain more (or one grain in all) would have thrown her into great peril, and made her condition alarming.

My experience with this drug has been peculiar. In 1861 I gave it to my own wife for threatened mammary abscess, and after three or four days' continuance her arms and all the surface of the upper part of her body broke out with a dense crop of tartar emetic pustules. The eruption was preceded by an indescribable and alarming sensation of numbness or deadness and tingling. To relieve this, brisk rubbing was resorted to, and in a few minutes the eruption came out thickly, bold, and distinct, but disappeared in a few days without further trouble.

Congenital Absence of the Faculty of Co-ordination.

To the New York Neurological Society (Oct. 5) Dr. G. M. Hammond presented a boy four years of age, brought to his clinic

on account of inability to walk. He was born at full term, the labor was natural, and he appeared to be perfectly healthy at birth. Shortly afterward he became sick, and continued more or less ill for six months. The attending physician diagnosticated colic. Since recovery from this attack, the patient had had no sickness. The special senses were normal; the patient understood as well as other children of his age. Perhaps he did not speak so plainly as he should, but two other children in the family, perfectly healthy, talked in the same manner. There was no history of syphilis. The patient was well formed, the muscles of the limbs were well developed for a child who did not walk, muscular reaction to both electric currents was normal, and the reflexes were normal. The only apparent reason for his inability to walk was want of power to retain his equilibrium. He could crawl on his hands and knees perfectly well unless he attempted to go very fast, when he would fall, and he always fell toward the right. He could stand, holding on to a chair, and walk pretty well if held upright. There was also inco-ordination in the upper extremities. He widened his base in standing. Dr. Hammond had not decided whether there was congenital absence of the sensory tract in the cord, or cerebellar disease.

Dr. Julius Rudisch had seen two similar cases—both in girls, one about eight years old and the other about thirteen. The first was seen some years ago and was under observation but a short time, and his recollection of the case was indistinct. But he had been impressed with what he took to be muscular weakness, not simply ataxia, but weakness in the back. The child, if sustained, could walk well; if not sustained, it would fall, like the boy presented by Dr. Hammond. The older patient could walk, but in a peculiar ataxic way, and in the position of marked lordosis. The legs were well developed, and for that reason he thought the trouble was in the muscles of the back. The cases were not, in his opinion, cases of congenital locomotor ataxia.

Treatment of Hernia of a Muscle.

The *Medical News* (Oct. 23) says:

This uncommon lesion consists in the protrusion of a portion of muscle through a rupture in its containing fascia. Two cases of this sort have recently come under the care of Giess, and he has made them the subject of an interesting communication in the *Berliner Klinische Wochenschrift*, No. 11, 1886. The first case was that of a man who had a hernia of the tibialis anticus muscle, caused by a blow with a stone. Palliative treatment by means of strapping and bandaging did no good, and Giess cut down on the hernia and removed the protruding portion of the muscle with scissors. After a few days the hernia had disappeared and suppuration came on. Giess then cauterized the protrusion repeatedly with nitrate of silver. The result was unsatisfactory, as the hernia persisted, although it was reduced in size.

In the second case a similar tumor was treated by incision, removal of the protrusion, freshening of the edges of the opening in the fascia, and suturing of the fascia with catgut. The superficial wound was also sutured, and the limb confined in a plaster-of-Paris dressing. The result of this operation was perfectly satisfactory. The wound healed by first intention; the plaster dressing was removed on the sixth day, and on the twenty-first day the patient left his bed with a solid cicatrix, and in a few days had full use of his leg.

The method adopted in this case seems rational, and the success which followed its employment by Giess confirms this impression.

Uterine Septic Infection.

Dr. Wm. P. Orr thus writes in the *Cincinnati Med. Jour.:*

In all cases of instrumental delivery where there is reason to fear septicæmia, the practice heretofore has been to syringe the vagina with a $\frac{1}{1000}$ solution of corrosive sublimate, and use a suppository of iodoform against the cervix. This plan, while it may be efficient so far as the cervix is concerned, amounts to only a half-way measure, in that the body and fundus of the uterus are not disinfected. The great bugbear has been the fear of iodoform poisoning, but as this is seldom met with in surgical practice, there is really no good reason why the same substance should not be as freely employed by obstetricians. The plan I propose is to dust the uterine cavity (including the cervical canal) with iodoform by means of an insufflating tube. For this purpose a hard rubber tube will answer best, as it can readily be bent by heat to any angle desired.

In non-instrumental delivery, when it is deemed best to use a mild disinfectant, I would recommend the oxide of zinc finely powdered.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——Beginning with January next, the *Archives of Gynecology, Obstetrics, and Pediatrics*, published by Leonard & Co., New York, will be issued monthly.

——A neat reprint has appeared of Dr. John H. Rauch's Address in State Medicine befere the American Medical Association last May.

——A small brochure on finger injuries, containing various useful hints, appears from the pen of Dr. J. T. Woods, of Toledo, Ohio.

——The Physician's Leisure Library is published by Mr. Geo. S. Davis, of Detroit. Its last issue is "The Physiological, Pathological, and Therapeutic Effects of Compressed Air," by Andrew H. Smith, M. D. Pp. 112. Price 25 cents. It is a good synopsis of the subject, and singularly cheap.

——Dr. W. M. Mastin, of Mobile, Alabama, sends an interesting article on venous blood tumors of the cranium, issued as a reprint.

——Messrs. Reed & Carnrick, New York City, have published a neat little book setting forth the diets suitable in various diseases, with special reference to beef peptonoids as an accessory.

BOOK NOTICES.

First Annual Report of the State Board of Health and Vital Statistics of Pennsylvania. Harrisburg, 1886. Pp. 356.

Eighth Annual Report of the State Board of Health of Illinois. Springfield, 1886. Pp. 556.

Both these publications are meritorious in a high degree, and illustrate how wide is the field which such boards can occupy, and how much solid good they do to the commonwealth which creates them.

The Pennsylvania report gives the official documents which put it into existence, and the proceedings of the meetings. The various appendices are occupied with reports on the sanitary condition of cities and towns in the commonwealth—a special and valuable discussion being that of the epidemic of typhoid fever at Plymouth, Pa., in the course of which Dr. French figures up its cost—figures that ought to be put very squarely at the legislators at Harrisburg, and at the civil officers of towns and cities. Then follow several excellent reports on quarantine and disinfection, and the forms, etc., which the board uses. A number of colored maps and plans are inserted, which add both to the beauty and usefulness of the report. One of these maps includes the whole State, and shows the relative density of the population, a matter of the first importance in statistical inquiries. A material and annoying defect in the volume is the absence of a table of contents. This reduces the value of the volume at least one-tenth.

The Board of Health in Illinois is one of the most efficient in the United States. In its services to the cause of medical education it far surpasses all others. The present report is a thick volume full of valuable material, well arranged and presented. In this also medical education in the United States receives particular attention, and a list is given of all the colleges in the country, with abstracts of their circulars. The volume also contains many important contributions to sanitary science.

Transactions of the Texas State Medical Association. Pp. 691. Austin, 1886.

This portly volume of nearly seven hundred pages, well printed and carefully edited, proves in the completest manner that the physicians of Texas are behind no others in their devotion to the progress of their science. The reports of the chairmen of the various sections on the progress of their respective branches are prepared with care, and in each section there are quite a number of original communications from physicians in the State. Nearly all of these contain valuable matter, and deserve preservation in the volume. It is, in all respects, a meritorious publication.

The Physician's Daily Pocket Record, by S. W. Butler, M. D., for 1887. Published by D. G. Brinton, Philadelphia.

The Medical News Visiting List for 1887. Lea Bros. & Co., Philadelphia.

The Physician's Visiting List for 1887. P. Blakiston, Son & Co., Philadelphia.

These three works are timely at this season, and all have their special advantages, which will be preferred by those who have become accustomed to them. That by Lea Bros. is the latest in the field, and has a more dressy appearance than the others, though the fact that it is larger in size will be a drawback in the opinion of many. Butler's Record has a spring clasp and perpetual almanac, which are favorite features with many.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

AN OFFICIAL REPORT ON CHOLERA.

On Thursday evening, November 18, by special invitation of the College of Physicians of this city, Dr. E. O. Shakespeare delivered an "informal *talk*" before that body, reviewing briefly the main points in his forthcoming official report on cholera. We can truly say that it has been many a long day since those who were present have listened to a "talk" so instructive and so interesting. We do not like to indulge in strong language, but we feel compelled to say that the mass of the profession of this city ought to be ashamed of themselves. To listen to this wonderfully interesting address less than one hundred doctors assembled, although the whole profession was invited. If it had been stated on the card of invitation that fried oysters, chicken salad, and champagne would be served free after the address, the neighborhood of the college would have presented a scene somewhat analogous to the late Chicago riots. We always knew that doctors had stomachs, and we realized that they had a perfect right to enjoy the good things of this world as much as any one else (even though the matutinal headache and sick stomach might follow), but we also imagined that they had brains, and we were foolish enough to believe that they enjoyed a somewhat higher order of cerebral development than is vouchsafed to the common mortal; but we fear that our exalted estimate of our glorious brethren has been placed a niche too high.

We venture to say that had Dr. Shakespeare made this "talk" in a small town, *every* physician for many miles about would have been there to listen. Of course we realize that some of our city doctors are so extremely busy that it would be impossible for them to attend such a gathering, ardently as they might wish so to do; but at the same time, we are equally sure that there were many men sitting idly in their offices who would have been both interested and (what is much more vital) instructed by this address. Dr. Weir Mitchell found time to be present, and proved, by his close attention, that he appreciated what was being said. Dr. Formad was present, and certainly there are many men in Philadelphia who stand much more in need of instruction than he does. So we could go on and mention the names of distinguished men who graced Dr. Shakespeare's valuable address by their presence; but the point we wish to emphasize by these exceptional instances is that in this particular case, as in the majority of instances, the men who would derive the most

instruction, because most in need of it, were conspicuous by their absence. We write thus plainly because we have an earnest desire that this apathy shall be dissipated. We do not wonder that society meetings are slimly attended; we have already given a reason for this, but, when such an exceptional literary feast as that of Dr. Shakespeare's is prepared, it is not only incomprehensible, but it is also positively disgraceful that the hall was not packed to overflowing. Let us be clearly understood. It might be inferred from what we have said that Dr. Shakespeare's audience was unexpectedly small. It certainly did come up to the expectations of those who made arrangements for it, as the hall was well filled; but we are somewhat sanguine in reference to the intellectuality of the profession, and we had expected to see a larger crowd than had ever before collected in "The College of Physicians." In this we were disappointed, and we can only reiterate that the profession of Philadelphia ought to be ashamed of itself.

OUR STATE BOARD OF HEALTH.

The physicians of Pennsylvania possess a most potent influence; they little realize how great their influence really is. Let the reader stop and reflect for a minute how important he is to his patient who may happen to be a member of the legislature; we do not mean how important from a purely *political* aspect, for, God save the doctor from politics!—but how much weight his voice will carry.

The State Board of Health *must* ask the next legislature for an increased appropriation. It now has $5,000 per year. Out of this the Secretary receives $2,000 for his annual salary—thus leaving $3,000 for traveling expenses, and scientific, or, indeed, all other work of the Board. That this is simply ridiculous, no one need be told. We were ten years getting such a Board; now that we have it, let us make it effective. It has only been in existence for eighteen months, yet it has done good work; give it money, and it will do much better.

In a word, the physicians of this State should organize themselves into a committee of one to urge upon the members-elect of the legislature the importance of a largely increased appropriation to this most *vital* Board. We do not mean $10,000 or $15,000; this Board ought to have at least $100,000 per year. Then would we see the Keystone State truly the national *Keystone* of Sanitation. The *little* State of Mississippi gives its State Board of Health $45,000 per year. Ought not this great and wealthy State to be ashamed of itself, if it does not liberally discount its small and comparatively poor neighbor?

Notes and Comments.

Painful Hypertrophy of the Breast Dependent upon Uterine Disease.

Dr. L. N. Sharp, of Minneapolis, Minn., writes to the *Med. Record:*

"In November, 1882, I was consulted by a lady for a painful tumor of the left mamma. She had been cared for by several medical men in a city sixty miles distant. She came to me, by advice of friends, with the diagnosis of cancer, and said her attendants had advised amputation of the breast as her only chance for recovery, but she recoiled from such an alternative. I looked the case over. She was thirty years of age, the mother of three children. She was well-built and fleshy; digestion good. The left breast was hypertrophied, the right one well developed, but only half the size of the left. The pain in the enlarged gland was excessive and constant, and the patient said she had not a good night's sleep for more than two years, because of the painful condition. The trouble began about three years before, the breast gradually enlarging and becoming more painful. On inquiry, I found she had uterine trouble, and I came to the conclusion that the hypertrophy was due to the uterine difficulty. I explained my views to her, and suggested an examination of the uterus. She declined an examination, and I declined prescribing. She then went to a city one hundred and fifty miles distant to consult a 'cancer doctor,' who told her he had never seen anything like her case, and dared not do anything for her. When she returned to her home, she was advised again by her friends to place herself under my care, and after some time concluded to do so. On examination, I found endo-cervicitis and erosion. She came under treatment in December, 1882, and as the uterus returned to its healthy condition the pain of the breast declined, the hypertrophy began to lessen, and by the following June the breast was about the size of its fellow, and entirely free from pain."

The Cause of Circular Gastric Ulcer.

Dr. Silbermann, of Breslau, has lately made some experiments on dogs for the pur-

pose of showing that the kind of anæmia characterized by deficiency of hæmoglobin in the red corpuscles of the blood is peculiarly favorable to the production and maintenance of circular ulcers of the stomach. Hæmoglobinæmia was produced by injection of various substances, and then either chromate of lead was introduced into a small gastric artery, or a ligature was applied to it, or the internal surface of the stomach was abraded by means of an œsophageal sound carrying a guarded point. All these animals were found to have contracted gastric ulcers, and it appeared to make no difference whether the hæmoglobinæmia was produced before or after the stomach was injured. With the microscope it was found that a number of the red corpuscles were of a very pale color, and that the blood was less alkaline than normal, which is explained by the experiments of Preyer, A. Schmidt, and Rollet, who have shown that hæmoglobin is a weak acid. Dr. Silbermann considers that in the anæmia or hæmoglobinæmia all the conditions are present which are required by various theories for the production of gastric ulcer—namely, arterial anæmia (Klebs), venous hyperæmia of the gastric mucosa (Key), venous stasis in the hepatic vessels (Gunsberg), circumscribed hemorrhages (Virchow), and, lastly, diminished alkalinity of the blood (Leube).

Brain Lesions following Injuries to the Head.

Popular thought attributes a great many diseases to the agency of falls on the head. Doubtless in many cases the fall and the disease are but accidentally related. But we believe that injuries to the head may be the potent agent in the causation of many cerebral lesions. The belief that traumatisms can cause blood extravasations with laceration of brain substance is of course well founded, but the doctrine that inflammations and new growths may arise as the direct result of injury can at best be based only on greater or less probability. If the fall or blow does not rupture vessels, and causes no obvious bruising of cerebral tissue, can it so disorder the molecular processes of nutrition as to lead to the formation of tumors? An interesting case of aphasia, with loss of "ear" for music, has been placed on record by Kast. A youth, aged fifteen, fell from a cart, and struck his head against the wheel. The accident was followed by loss of consciousness, which lasted several hours, and on restoration to consciousness it was found that the right side of the body was paralyzed, and that, though he seemed to comprehend what was said to him, he could not utter a word. The paralysis slowly disappeared. At the end of two months the aphasia had altered its characters. The boy was no longer unable to say some words, but he had completely lost the artistic use of his vocal cords, though prior to his accident he was a distinguished member of a choral society. Thus he sang falsely and out of tune, and could not correctly follow the lead of another singer. After the expiration of two years, however, he regained perfectly, so it is said, the artistic use of his voice, but still remains largely aphasic as to the employment of words for the construction of sentences.

Asphalgesia in Hysterical Patients.

Dr. A. Pitres, of Paris, has been carefully watching the case of an hysterical patient affected with hemi-anæsthesia of the left side. Pinching, burning, or pricking her on the left side does not produce pain; but if she touches any copper article, her hand contracts, and intense pain is felt, which, if prolonged by contact with that metal, produces a convulsive attack. In two other cases, during wakefulness, the patients were unable to touch either silver or copper without experiencing the sensation of being burned. Dr. Pitres speaks of this curious phenomena under the title of asphalgesia. It is rare to meet with these symptoms in hysterical patients during the period of wakefulness, but they are very general during hypnotic sleep. In the greater number of patients with whom it was possible to induce hypnotic sleep, it has generally been found that, on their touching any metal, a painful sensation, as of burning or of a violent electric shock, was felt. Some patients only experience these sensations on touching certain metals; others are affected in the same manner on touching any glass object. Generally, asphalgesia is present on both sides of the body, whether the patient be affected with only hemi-anæsthesia or hemi-analgesia; but no rule can be given for these symptoms, as, in some cases, painful sensations produced by the contact of any metal may likewise be felt on the side of the body where the sensibility is normal.

An India-Rubber Catheter in the Male Bladder; Successful Removal.

Wm. M., aged sixty-three years, farmer, near Belfast, Ireland, suffered for the past three years from retention of the urine due

to enlargement of the prostate gland, which required him to use an India-rubber catheter. Whilst passing the catheter on the evening of June 6, 1886, it accidentally slipped into the bladder. Being called in consultation, Dr. Henry O'Neill (who reports the case in the *Lancet*) found the patient had been suffering from complete retention of urine for thirteen hours and a half. Having placed the patient on his back and administering methylene from Junker's apparatus, he introduced into the bladder a small Thompson's lithotrite, and after searching carefully for some time, succeeded in extracting the catheter, which was about nine inches long, and in size about a No. 12. After its extraction, on drawing off the urine a small amount of blood was mixed with it. The bladder was carefully washed out with warm water, using Clover's suction syringe. The patient was given one-tenth of a grain of morphia, and the next day a gentle saline aperient was administered. He had the urine drawn off regularly and the bladder washed out with solution of sulpho-carbolate of soda (half a grain to the ounce) twice a day. A poultice of linseed meal was applied over the hypogastrium and kept on for two days. Three days after the operation he was reported as improving, with no bad symptom, and at the end of nine days was going about his usual duties.

Syphilis from Vaccination.

Dr. J. S. Prettyman, Jr., of Milford, Del., reports the following case to the *Medical Record:*

"Mr. N. T., aged thirty, has been married nine years. His wife is healthy, has never aborted, and is entirely free from skin disease. They have two robust children, aged six and eight, who have always been well, but are subject to a 'breaking out.' Ten years ago the patient vaccinated himself directly from the arm of another, who, it is said, had been cured of a 'bad disorder.' In about two weeks an eruption appeared over the entire body, and continued three months, disappearing and re-appearing several times since. From time to time lumps have been noticed over various parts of the body. He has never had ulcers in the throat, but the glands have been enlarged, and several times chronic abscesses have formed. He received no treatment, except such remedies as he would apply locally. He came to my office October 13, with nodes, bullous syphiloderm, and ulcerations upon the neck, arms, back, and legs. He denied all possibility of contagion from any other source, and affirmed that previous to the vaccination and appearance of the eruption he had not even once indulged in sexual intercourse."

Acute Pneumonia in Utero.

Dr. Henry Strachan thus writes in the *Brit. Med. Jour.:*

I am not aware whether the following case is the first recorded—I have been unable to find any account of a similar one; but whether that be so or not, it seems to me of great interest, and worthy of being placed on record:

A patient, Nancy M., was admitted into the hospital under my care in December last, suffering from acute pneumonia (whole of left lung), and a history of illness covering the four days previous to admission. She was eight months pregnant.

On the evening of the day of admission, her temperature was 103.6° Fahr., and she was delivered of a female infant. The infant died in less than twenty-four hours after birth, with symptoms of acute pneumonia. A post-mortem examination showed acute pneumonic consolidation of the whole of the left lung. The mother made a rapid and good recovery.

Whilst there is ample evidence that the other acute specific diseases (so-called "fevers") are capable of being transmitted by the pregnant woman to her offspring yet *in utero*, this is the first time I have had any evidence that the "acute pneumonic fever" could also be so transmitted.

Malformation of Intestine.

Mr. William Thomas exhibited to the Midland Medical Society the stomach and intestines of an infant, five days old, that had been operated on for obstruction. The stomach was of normal size; the duodenum became gradually enlarged as it reached its termination; the jejunum was very large, and formed dilated coils, which had distended the abdomen. It had been opened twenty-two inches from the pylorus, for the relief of the obstruction, and, ten inches further, it terminated in a blind extremity. The small intestine recommenced almost immediately between the layers of the mesentery, being about the size of an ordinary pencil; it formed several coils, and, extending for thirty-six inches, terminated in a well-formed cæcum, from which a perfect, though contracted, colon, could be traced to the anus. The various parts of the intestine were so

firmly matted together by well-organized bands of lymph, the result of previous intrauterine peritonitis, that the relation of parts could not be made out until the intestine was removed from the abdomen. The child was somewhat relieved by the operation, and lived for about eighteen hours after it.

Pulmonary Phthisis and Ovarian Disease.

It is a somewhat novel idea which Dr. B. Fenwick sets down in the following conclusion of an article in the *Lancet*, October 23:

"In conclusion, I venture to believe that I have shown the distinct probability that the great predisposing cause of ovarian disease is a family tendency to phthisis, and that gestation may be the exciting cause. But in view of the immense importance of the subject, both to the profession and the public alike, as regards questions of diagnosis and prognosis, and the still greater matter of prevention, I would earnestly appeal to all who in future have to treat cases of ovarian cystoma either to publish as complete as a family and previous history of each, or to favor me with the notes, which, of course, I would duly acknowledge. A thousand well recorded histories would definitely settle the important points I have touched upon by the hard logic of manifold facts. I should not base implicit confidence upon a smaller series. Straws show how the wind blows, but mathematical precision can alone determine its force."

Chromic Acid vs. Galvano-Cautery.

M. Poskin has reported to the Liège Medical Society on his use of chromic acid in more than 100 cases of diseases of the nose, pharynx, and larynx, as showing the great value of this powerful caustic in hypertrophy of the turbinated bones, polypi, and granulations in the ears. He remarks that, as it is a violent poison, acting especially on the gastro-intestinal tract, it is necessary to exercise great caution, especially in pharyngeal and laryngeal cases; and he eschews it altogether in the case of children. Its action may be neutralized by a weak solution of carbonate of soda. The best way of employing chromic acid is to heat moderately a very small crystal on a silver probe, to which it will adhere as a dark-brown coating. If the heat is too great a green oxide is formed, which is devoid of any caustic action. M. Poskin finds that chromic acid compares favorably with the galvano-cautery, both on account of the cost and the convenience with which it may be applied. It is, he thinks, also quite as efficacious and less dangerous. The eschar which is produced falls in from three to five days.

Cantharides in the Bites of Rabid Animals.

Dr. Karchevski mentions in the *Russkaya Meditsina* that he has successfully treated some patients who had been bitten by a rabid wolf, with cantharides. The wolf attacked three men, inflicting on the first a large and deep wound in the left groin, a piece of skin several square inches in area being torn off. The other men were wounded in the face, legs, and arms, but more superficially. Still the bites of a rabid wolf are well known to be peculiarly dangerous. Dr. Karchevski remembered a conversation he had had with Professor Lashkevich, in which the latter had suggested cantharides as a remedy in hydrophobia, and he therefore made up his mind to give it a trial. Cantharides plasters were applied to all the wounds, and powdered cantharides was administered to each of the three patients in doses of a grain a day. The internal administration was continued for a week, till the patients complained of some heat in the urethra. Seven months having passed, and all the patients being still perfectly healthy, the author thinks the cases worth recording, though he is quite aware that *post hoc* is not necessarily in this instance *propter hoc*.

Lanolin as an Ointment Basis.

The following statement by Professor Widerhofer is reprinted by the *Fortsh. d. Med.* from the *Allgem. Wiener Med. Zeitung:*

"The eczema which you see about the elbow-joint of this child will be thus treated: It will be rubbed with soap and wet flannel till a lather is produced, then wiped dry; and then will be wrapped round night and morning with linen thickly smeared with lanolin, having five per cent. of bismuth subnitrate added. Lanolin salve is a most excellent remedy for eczema in children; for it is readily tolerated by the skin (in the case of little children especially), on account of its forming very heavy fatty acids; whilst other fats (and vaselin) form very light fatty acids on coming in contact with the skin, and in children the skin is very sensitive to fatty acids."

Treatment of Ingrowing Toe-nail.

Dr. Philip Miall writes to the *Brit. Med Jour.* that he has for many years used tan-

nin for ingrowing nails, and does not find rest necessary. A concentrated solution (an ounce of perfectly fresh tannic acid dissolved in six drachms of pure water, with a gentle heat) must be painted on the soft parts twice a day. Two cases recently had no pain or lameness after the first application, and went about their work immediately, which they could not before. After about three weeks of this treatment, the nail had grown to its proper length and breadth, and the cure was complete. No other treatment of any kind was used, though formerly he introduced lint under the ingrowing edge in such cases.

Note on Cocaine.

Dr. George Elder thus writes in the *Lancet*, October 30:

Cocaine is now so extensively used in minor surgery, and usually with such happy results, that an experience like one I had the other day will come upon most of us as a disagreeable surprise.

Preliminary to opening a superficial abscess, twelve minims of a freshly prepared 10 per cent. solution were injected under the skin; and three or four minutes afterwards syncope supervened, followed by twitchings of the face, falling of the jaw, coldness of the body, clammy perspiration, lividity of the face—in fact, all the appearances of imminent death. The patient was several minutes in recovering consciousness, and during the remainder of the day felt very prostrate. Several similar occurrences have been noted in ocular surgery from time to time, showing that cocaine is not so innocuous as has been generally supposed.

A Bullous Eruption Caused by Salicylic Acid.

Dr. Rosenberg reports in the *Deutsche Medicinische Wochenschrift* a case of rheumatism treated successfully, as regards the articular pains, with salicylic acid. But the patient complained of a severe burning of the skin, and the body became covered with purplish spots. The medicine was discontinued for a time, but on another trial, a month later, the same sensation was complained of, and in addition to the discoloration of the skin there appeared a number of large blebs filled with serum, situated on the back and extremities, and also upon the conjunctiva and mucous membrane of the tongue and lower lip. A third trial resulted in a precisely similar eruption. Examination of the fluid in the blebs failed to reveal the presence of salicylic acid.

Ether Spray in the Reduction of Hernia.

Dr. George R. Fellows, of Moose River, Me., writes: "About two years ago was called to see a case of strangulated hernia of two days' duration. Two physicians had been called, but were unable to reduce the hernia by ordinary means. The patient was suffering terribly, but was unable or unwilling to take opiates of any kind. Thinking to relieve the pain, I sprayed the hernia with ether, using a common hand-atomizer, and was greatly surprised to find the hernia disappearing spontaneously. Since that time I have used ether spray in strangulated hernia in several cases, always with the best results, the operation being painless, and reduction occurring spontaneously or with slight pressure."

Use of Lanoline in Midwifery Practice.

Dr. C. Clark Burman calls our attention through the *Lancet* to lanoline as a particularly efficient means of reducing the rigidity of the perineum in primiparæ. Owing to its penetrative and softening properties, he finds it much preferable to the plan adopted of friction with pure lard. Only recently this rigidity was strongly marked in an elderly primipara, where the forceps were required on account of debility on the part of the patient. He was surprised with what facility he succeeded in reducing it so as to enable him to apply the forceps much sooner than he should otherwise have felt justified in doing on account of the danger of severe laceration.

Expulsion of Thread-Worms.

In treatment of thread-worms in children, Dr. Sidney Martin (*Pract.*, Lond., October,) finds the following most useful:

℞.	Tincturæ rhei,	♏iij.
	Magnesii carbonatis,	gr. iij.
	Tincturæ zingiberis,	♏j.
	Aquam,	ad. ℥j.

Given twice or three times daily, according to the effect on the bowels.

In most cases the ordinary injections of salt and water, infusion of quassia, etc., may be dispensed with: these, the writer thinks, do good for a time, but often fail to relieve the attendant symptoms, which are usually very irregular, and in some cases severe.

The Galvanic Cautery in the Treatment of Membranous Dysmenorrhœa.

At the recent meeting of the Association Française pour l'avancement des sciences (*Ann. de Gynéc.*), M. Landowski expressed

the opinion that, while membranous dysmenorrhœa generally depended on a particular diathetic state or on general debility, local treatment should not be neglected. He stated that for some time past he had been successful with the galvanic cautery, which, heated to a dull red, he applied to the endometrium, the cervical canal having previously been dilated. He makes the application five or six days after the cessation of a menstrual flow, and the patient remains in bed for about eight days.

Mixture to Stop Falling of the Hair after Typhoid Fever.

Bouchard (*Le Concours Médicale*) recommends the following:

℞.	Ol. ricini,	7 grams.
	Goudron,	2 "
	Tinct. benzoini,	20 "
	Chloroformi,	30 "
	Alcohol,	1,000 "

Correspondence.

Charms and Superstitions in the Treatment of Diseases.

Eds. Med. and Surg. Reporter:

My *own personal* experience with "charms and superstitions in the treatment of diseases," was in a certain case very sad indeed.

Once upon a time I found the following message written upon my office slate: "mises S—— is nearly ded cum rite of." I galloped to the scene of disaster, and as soon as I entered the room where my services were so very urgently demanded, I made an instantaneous diagnosis—*post-partum hemorrhage*—for I saw upon the bed a woman the expression of whose face showed that she was almost completely exsanguinated, and around whose little fingers and throat pieces of red yarn had been tied. Around the stove sat two or three granny-women, taking a social smoke, and discussing the best way to dress the "nable" of the yelling infant, whose primary ablutions had just been completed *secundum* (their) *artem*. The husband and father stood at the foot of the bed, unwinding from a ball some more of the remedy, evidently intending to continue treatment by the application of another and larger dose.

Alarmed, I made long strides to the bedside. With one hand I felt the patient's pulse, with the other I felt over the suprapubic region for her uterus, and with my right big toe I felt *something very cold and sharp*, which forced me to retreat one pace. Looking down at my boot I saw a nice clean cut, 2.5 inches long, across the toe, through which *my life's blood* was welling. I immediately sought for the *fons et origo* of this second case of hemorrhage so unexpectedly thrown into my hands (or foot rather), by lifting up the bed curtains, and there lay an *axe!* Inquiring in no choice terms of paterfamilias why that implement was there at such a time, I was informed by him that "We put it there to stop *her* from bleeding!"

The patient made a good recovery, the incision in my toe united by first intention, but the boot shows an ugly, disfiguring, and dragging cicatrix to this day.

Louis Schneider, M. D.
20 *W. 4th street, Williamsport, Pa.*

News and Miscellany.

The Partial Responsibility of Persons Mentally Affected.

At a meeting of the Academy of Medicine of Paris, M. Ball made some observations on the partial responsibility of persons mentally affected. A recent trial in France had again, he said, drawn the attention of lawyers and judges to a question which had always opened up much controversy, namely, the moral responsibility of the insane. A great number of persons mentally affected retained a certain degree of intelligence, and to a certain extent were guided in their actions by the same instincts and motives as persons in full possession of their reason; thus, the same principles of common law might reasonably and in all justice be applied to them. How, then, was partial or limited responsibility to be defined? Apart from criminality, the moral responsibility of the insane would not be contested, and the converse was even more obviously true. Men of the greatest genius and celebrity had shown indubitable signs of mental alienation, but this fact had never been used to diminish their merit, or to deny them due gratitude. Newton propounded his system notwithstanding his having passed through a phase of insanity. Auguste Comte was none the less a great philosopher for having been temporarily confined in a mad-house. If lunatics were open to approval or praise, were they not equally open to censure, and should neither condemnation nor punishment be ever allotted to them? There is, therefore, nothing absurd, as had been affirmed, in the assertion that criminal lunatics exist.

Without wishing to shake the foundations of law, it might be said that the ancient idea of responsibility had been replaced by the more modern and more physiological notion of individual predisposition. Without asserting, with a celebrated alienist, that all criminals were lunatics, there was yet an increasing tendency to consider them a race apart. Great saints, great heroes, and great criminals, said Professor Benedict, in London, were beings outside the ordinary run; they constituted a complete anomaly in human nature.

From the point of view of public utility, Dr. Ball remarked that, if the doctrine of the irresponsibility of the insane, upheld by a considerable number of men in authority, and taken up by modern observers, were to have the support of the law, singular privileges would be suddenly conferred upon a whole class of individuals, more numerous and more dangerous than was generally believed. The outcast, the vicious, and the eccentric would never want alienists ready to raise them to the dignity of lunatics. The justification of punishment was its deterrent power. It was justified by the feeling of fear it inspired in ill-constituted organizations; it was a barrier of defence raised for the protection of honest individuals, who had also some claim to the sympathy of the legislator. No *phrenometer* (according to the ingenious expression of M. J. Fabret) existed for measuring the degree of responsibility that each individual of this category might lay claim to. Moreover, was it not apparent that the same reasoning might be applied to ordinary criminals; and that, in order to satisfy logic, all punishment must be suppressed? Lunatics undoubtedly existed, who, without possessing a complete notion of good and evil, yet had a very clear perception of the danger of being subjected to punishment. Dr. Ball, in conclusion, expressed himself in favor of the doctrine of moral responsibility.

A Thousand Sheep Poisoned.

The mail from South Africa brings tidings of another of those wholesale poisonings of sheep that have happened from time to time, filling the minds of the farmers with consternation in the localities where they occur. This time it is a farmer in the Bloemfontein district whose stock has been so ruthlessly destroyed, and to the extent of nearly a thousand sheep. The particulars of the case must be of special interest to all owners of sheep. The dip used was one of the best known of the class distinguished as powder dips (arsenical), and has long had the reputation of being prepared with great care. We believe the farmer used it with some degree of confidence, in face of the printed statement with each package to the effect that this powder dip might be used with perfect safety if the directions were followed. Unfortunately, the results have contradicted this. The directions were followed with ordinary care, yet nearly a thousand of the sheep dipped were poisoned. How did this occur? It appears the sheep were suffering from scabs, and twice dipping at an interval of a fortnight was considered desirable. A large dipping-tank was used, that contained some of the solution of the same dip held over from a previous dipping. This was added to in the usual manner, and the flock was dipped. Owing to the hot weather or some other cause, this dipping caused some soreness and inflammation of the pelt (or skin of the animal), but much attention was not paid to it. The sheep were dipped a second time, as recommended in the directions accompanying the dip, with the result that afterwards nearly a thousand of them died, and in great agonies, caused, as has since been proved, by the absorption of arsenic through the skin.

The Japanese and Quarantine.

The intelligent and independent judgment exhibited by the Japanese in their application of knowledge acquired in Europe and America is well exemplified by the port sanitary regulations, which the *Indian Medical Journal* states to have been enforced during the prevalence of cholera in 1885. All vessels from infected localities were subjected to medical inspection before any communication with the shore was allowed; if the crew and passengers were found healthy, the vessel was allowed to proceed; if there were cases of cholera on board, or the corpses of persons who had died of cholera, the vessel was detained, the patients removed to hospital, and the corpses burnt, or buried after being disinfected, according as the friends preferred; the vessel and the crew and passengers were disinfected, and then allowed to proceed. These reasonable regulations, founded upon a scientific knowledge of the disease and of the nature of infection, are in striking contrast with the panic-stricken haste with which many European nations impose their so-called "rigorous quarantine." The Japanese appear to possess the rare power of learning from the experience of others.

The Proposed Rush Monument.

The committee in charge of the subscription has issued a circular which concludes as follows:

"It may be approximately estimated that $40,000 will be sufficient to erect a monument that will be fitting and unexceptionable as a work of art, and it does not admit of question that this sum can be speedily raised among the 106,000 physicians and students of medicine in the United States. That no one may be debarred the privilege of contributing, a subscription-rate of one dollar from each individual has been determined upon, and you are accordingly solicited to remit that amount to the member of the committee representing the State, Territory, or national service to which you belong, who will also receive voluntary donations of such other sums as may be tendered by persons interested in this national undertaking."

The New York member of the committee is Dr. A. N. Bell, and the treasurer is Dr. Joseph M. Toner, of Washington.

The Vienna Hospitals.

In the Vienna hospitals some form of tuberculosis is found in nearly 70 per cent. of the deaths. The treatment of acute diseases is generally expectant, and in typhoid fever, milk and other liquid diet is used. Previous to 1879, when the city obtained its water from the Danube river, typhoid fever was almost epidemic in Vienna. In that year they put up new water works, and since that time not one case has developed in the city. A bacteriological laboratory is connected with the pathological department, and cultivations of bacteria are made from typhoid fever, pneumonia, erysipelas, glanders, septicæmia, and other diseases. Experiments with bacterial cultures are made upon lower animals. Nearly every department of the hospital now has a bacterial laboratory, and the search for new forms and confirmation of already discovered bacteria goes on with enthusiasm.

International Exhibition at Barcelona.

An International Exhibition is to be held at Barcelona between the months of September, 1887, and April, 1888. The exhibition, which will be opened on September 15, and remain open for at least six months, will admit all agricultural, industrial, and commercial products, and will have a special section for shipping, fine arts, electricity, medicine, and hydropathy. It is to be held in the park and adjacent grounds belonging to the municipality, in the vicinity of the French and Tarragona railways, and will cover an area of 300,000 square metres. Arrangements have been made with the Spanish railway companies by which a rebate of 50 per cent. will be granted on the rates generally charged on all goods conveyed by their lines for the purpose of being placed in the exhibition, and negotiations for obtaining similar concessions have been opened with foreign railways in connection with the Spanish lines.

The Alcoholic Red Nose.

The Church of England Temperance Chronicle states that the following appeared among the miscellaneous advertisements in a recent issue of the *Irish Times:* "How to Change the Color of an Alcoholic Red Nose.—Recipe, which is effectual in nine cases out of ten, may be had by sending postal order for 10*s.* to 'K.,' 738, this office." There is a very watchful worker in Dublin in the person of Mr. T. Wilson Fair, the energetic Hon. Secretary of the Dublin Total Abstinence Society, so it is not a matter for surprise that the quaint advertisement above quoted was immediately followed by this: "How to Change the Color of an Alcoholic Red Nose.—Don't waste 10*s.* Call over to the Coffee Palace, 6 Townsend street, and in 99 cases out of 100, if you sign the pledge and keep it, your nose will assume its natural shape and color.—Alcoholic Red Nose Curing, 6 Townsend street, Dublin."

The New Surgeon-General of the Army.

Lieutenant-Colonel John Moore, who was formerly Assistant Medical Purveyor, has been appointed Surgeon-General of the Army. Surgeon-General Moore is a native of Indiana, from which State he entered the medical corps of the army in 1853. His first active service was at Fort Meade, Florida, where he relieved Dr. W. A. Hammond, during the second Seminole war. He attained to the rank of major in 1862, and was brevetted lieutenant-colonel in 1864, for gallant and meritorious service during the Atlanta campaign, and the following year, having served as a medical director, he was brevetted colonel, for faithful and meritorious service during the war. For some time past he has been Assistant Medical Purveyor and Acting Medical Storekeeper at San Francisco. He was the fifth on the list of lieutenant-colonels of the medical corps in the line of promotion.

The Austrian Medical Association.

The Austrian Medical Association, which now comprises twenty-six branches, with a total of 4500 members, recently held its seventh annual meeting at Innsbruck, and resolved to petition the Government to make vaccination obligatory throughout the empire by imperial statute, also to restrict the privilege of private practice to medical men who have already served in a hospital. The Association expressed an opinion that considerable changes were desirable in the regulations concerning the training of medical students; and, lastly, a request was preferred that a law should be made assigning substantial pensions to the widows and orphans of medical men who might meet with their death through attending to their duties during an epidemic.

The Length of a Step.

Dr. Gilles de la Tourette has recently published a monograph upon normal locomotion and the variations in the gait caused by diseases of the nervous system. He found, from a comparison of a large number of cases, that the average length of a space is, for men, twenty-five inches; for women, twenty inches. The step with the right foot is somewhat longer than that with the left. The feet are separated laterally in walking about four and one-half inches in men, and about five inches in women. The ataxic gait is characterized by an actual shortening of the pace coinciding with an apparent lengthening, and by a considerable increase in the lateral separation of the feet.

The Occupations of Great Men.

The *Med. Age* says that the father of Demosthenes was a blacksmith; of Euripides, a dealer in vegetables; of Socrates, a mediocre sculptor; of Epicurus, a shepherd; of Virgil, an inn-keeper. Columbus was the son of a wool-carder; Shakespeare, of a butcher; Luther, of a miner; Cromwell, of a brewer; Sixtus V., of a swineherd; Linnæus, of a poor country minister; Franklin, of a soap-boiler; Rousseau, of a watchmaker; and Murat, of an inn-keeper. The mothers of these men may have been the source from which their genius was derived, and, indeed, it is known that some of them were women of more than ordinary excellence.

Fever in India.

Fever was very prevalent in the Central Provinces last year, causing no fewer than 17,634 out of the total number of deaths (301,684), or a ratio of 197.35 per mille. The officiating Chief Commissioner has requested the Sanitary Commissioner and the Civil Surgeons to direct renewed attention to the distribution of fever, whether it prevails most in jungly or in cultivated tracts, on highlands or lowlands, on black cotton soil or elsewhere. The effect of a break in the rains is also a point which will be carefully observed.

Gigantic Seaweeds.

Some of the gigantic seaweeds have stems which exceed in length any of which terra firma can boast. Recently the ship "Clever," commanded by Capt. John Stone, arrived at Montevideo with a portion of a seaweed which had been picked up in the Atlantic near the equator. The sailors perceived an object floating on the surface some distance from the ship, and, manning a boat, they rowed to it, and ascertained that it was an alga of enormous size. On measuring it, it was found to have a length upward of fifteen hundred feet. It has been identified by botanists as Macroceptis pyrifera.

Restrictions on Veterinary Practice in France.

The French Minister of Agriculture has drafted the following resolution, which has since become a law: "No one who is not in possession of a diploma in veterinary medicine, granted to him by a French veterinary school, shall practice this branch of science in France." Any breach or evasion of this law is punished by a fine of from sixteen to four hundred francs for the first offence, and if the offence be repeated, a double fine, with from six to thirty days' imprisonment.

Half Rates to Pasteur's Patients.

In consequence of the number of petitions forwarded through several prefèts, M. Tarrien, the Minister of Public Works, has informed them that the railway companies have consented to transport Pasteur's patients both ways at half-price in third-class carriages; but the request for such a favor must be accompanied with a certificate of the mayor of the locality to the effect that the patient is assisted by the commune.

A Professor of Philogeny.

It will be remembered that some time ago Herr Paul von Ritter, of Basle, gave the sum of 300,000 marks to the Jena Univer-

sity for the furtherance of scientific inquiry on the basis of Darwin's theory. It has now been decided to employ half the interest in the maintenance of a "Ritter Professorship for Philogeny." The chair is to be filled by Dr. Arnold Lang, formerly scholar and assistant of Professor Häckel, of Jena University.

Sponge-grafting; What Becomes of the Sponge?

An interesting article on this subject, by Dr. John C. Cotton, of Meadville, Pa., which was published in the MEDICAL AND SURGICAL REPORTER (June 12, 1885,) has been extensively noted, principally by the *Provincial Medical Journal*, of Leicester, England, from which it was again copied by the *N. E. Medical Monthly*, and again by the *Cincinnati Medical Journal*.

Forty Thousand New Doctors in Ten Years.

The *Medical Record* says that in the last nine years 103,598 persons have matriculated as medical students, and one-third of these, or 33,684, have become doctors of medicine. At this rate the total number of doctors for the decade will be nearly forty thousand. For making these, the medical colleges must have received over twelve millions of dollars.

The University of Pennsylvania.

An association of the alumni of this institution residing in New York city was recently organized, and on Tuesday evening, November 23, the event was celebrated by a dinner at Delmonico's, at which the Provost, Dr. William Pepper, Dr. Leidy, and a number of the graduates of the medical department were present.

An Expensive Experiment.

In the early days of cocaine investigation, its toxic power was tested on a dog, and forty grammes were required to kill the animal. The cost was eight hundred marks, or about one hundred and sixty dollars.

Electricity Utilized as a Means of Punishment.

An ingenious Swiss is said to have devised an electrical whipping apparatus which will inflict the requisite amount of pain without causing unsightly and inconvenient wheals.

—It is reported that diphtheria is epidemic in the town of Ishpeming, Mich., and that public gatherings have been prohibited, and the schools and churches closed.

Personal.

—Dr. Wm. S. Little, of Philadelphia, is spending the winter at Aiken, S. C., where he will be pleased to attend to ophthalmic cases which may be recommended to his care.

—At the recent celebration of the two hundred and fiftieth anniversary of the establishment of Harvard University, the following named members of the medical profession were among those on whom the degree of LL. D. was conferred: Professor Joseph Leidy, of the University of Pennsylvania; Dr. S. Weir Mitchell, of Philadelphia; and Dr. John S. Billings, of the army.

Items.

—The Paris Exhibition of 1889 is being organized. The Commission have commenced their sittings, and a guarantee fund of 22,000,000 francs has been subscribed.

—An amusing prescription, too good to keep, is appended:

Oxvomit and Black antney,
mixed witht flaxseed,
Will coar colrey on chickens.

—"Johnny, here you are at the breakfast-table, and your face is unwashed," said his mother.

"I know it, ma. I saw the animalculæ through pa's microscope in the water last night, and I ain't going to have those things crawling over my face with their funny little legs."

—Dr. William Goodell, of this city, has performed thirty ovariotomies within the last year, with only one fatal result out of the whole number. As these were not selected cases, such a series will compare most favorably with any heretofore reported.

—At Prof. Da Costa's clinic recently was a very marked case of *hysteria*, the patient suffering from hyperæsthesia of the skin, trembling paralysis, and "fits." Treatment: Strengthen patient's *morale*, and encourage her; have her exercise short of fatigue; plenty of good food and rest in bed; and let her take zinci valerianas gr. ij ter die. In eleven days she returned practically cured.

QUERIES AND REPLIES.

PREVENTION OF APOPLEXY.

SOLUBLE

PILLS AND GRANULES

UNEQUALLED FOR
Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distributed.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

DR BUCKLAND'S
SCOTCH OATS ESSENCE

NATURE'S NERVE TONIC AND BRAIN FOOD.

Yielding the most remarkable results in both Functional and Organic Diseases of the Brain and Nerves, especially

NEURALGIA,	OPIUM and MORPHINE HABITS,	SPERMATORRHŒA,
INSOMNIA,	INFANTILE PARALYSIS,	TIC DOLOUREUX,
SCIATICA,	NERVOUS DYSPEPSIA,	MELANCHOLIA,
MANIA,	NEURASTHENIA,	IMPOTENCY.

FORMULA.—Avena or Avenesca, the active principle of the Oat (Avena Sativa) obtained by crushing the grain (dried in vacuo), with pure alcohol, skimming off the fatty scum obtained by ether washing, evaporating to dryness, and then dissolving the amorphous powder (Avena) with boiling alcohol and flavoring. The dried grain is then treated by maceration and percolation from 96 to 144 hours. The final solution is of a 3½ per cent. strength.

☞Most remarkable cures of the OPIUM HABIT.
☞The most active tonic to both male and female SEXUAL ORGANS known.
☞Almost Specific in IMPOTENCY and SPERMATORRHŒA.
☞As a Brain and Nerve Tonic and Restorer of Wasted Energy it is unparalleled.

Put up in 3 oz. bottles. Price, $1.00. For sale in all drug stores.

CONJUNCTIVAL AFFECTIONS.

BY WILLIAM F. MITTENDORF, M. D.,

Of New York City.

Inflammations of the conjunctiva constitute about fifty per cent. of all diseases of the eye. These troubles vary considerably in regard to their extent and severity, and derive their special importance from the fact that the great majority of them are contagious. Diseases of the conjunctiva may be, therefore, divided into non-contagious and contagious. In the latter class of cases, the causative agent of the contagion has not been accurately defined up to the present time. It is true there has been found a special micrococcus in granular lids; and likewise in gonorrhœal ophthalmia the gonococcus of Neisser has been found in the secretion of the eye; but in the great number of catarrhal affections, which are undoubtedly also contagious, no specific organism has as yet been demonstrated. Formerly the idea prevailed that all the secretions of the eye containing any purulent ingredients, and especially pus corpuscles, were contagious. It is possible that the pus corpuscles are particularly adapted to serve as the carriers of the micrococcus or of the contagious principle.

Contagious affections of the conjunctiva are all those in which there is a muco-purulent secretion. The virulence of the contagion depends upon the nature of the discharge; as a rule, the more pus it contains the more contagious it seems to be, and there are only a few diseases of the conjunctiva which are, therefore, not contagious. These are, in the first place, *phlyctenular conjunctivitis*, which, as you know, is a localized affection. It does not affect the whole of the conjunctiva, and is especially characterized by the formation of one or more phlyctenular ulcers, nearly always on the conjunctiva of the eyeball, but sometimes on the cornea itself.

Another form of conjunctivitis which as a rule is not contagious, is *traumatic conjunctivitis*. A slight burn of the eye or a foreign body embedded in the conjunctiva, will set up sufficient irritation to cause a mild form of conjunctivitis. Very mild forms of catarrhal conjunctivitis, depending especially upon irritation, such, for instance, as we find in conjunctivitis accompanying errors of refraction, which some authors speak of as simple hyperæmia of the conjunctiva, are not contagious. But all severe *catarrhal inflammations*, as well as all acute purulent forms of conjunctivitis, of which we have *purulent ophthalmia*, the *blennorrhœa neonatorum*, *gonorrhœal ophthalmia*, are very contagious. Less contagious, but still very dangerous, are those affections which are chronic; and of these we have two varieties, the *chronic blennorrhœa* of the conjunctiva, which is characterized especially by hyperplasia and excrescences of the epithelial layer of the conjunctiva; and *granular lids*, or *Egyptian ophthalmia*, which is characterized by an accumulation of lymph-cells in certain portions of the conjunctiva.

Let us consider the etiology of these diseases.

Catarrhal conjunctivitis is easily brought about by sudden changes of temperature, by chilling. This is especially apt to occur

in the spring and fall, and these are the seasons in which we meet with the large majority of acute catarrhal diseases of the conjunctiva. Some of these forms of conjunctivitis, more sub-acute but very obstinate in their course, have therefore derived the name of *vernal* or *autumnal catarrh* of the conjunctiva, and they are characterized by participation of the bulbar conjunctiva, and especially that portion which surrounds the cornea, as well as the limbus. A thickening of the limbus, with an infiltration around the sclero-corneal margin, are the principal features of that form of catarrhal conjunctivitis which is known as spring or autumnal catarrh. Another form of this disease in which both the conjunctiva of the lids and of the eyeball are implicated, and in which on account of this participation of the bulbar conjunctiva the eye is of a marked bright red appearance, is known as *pink-eye.*

A third form of catarrhal inflammation is that in which the seat of the disease is especially in the fold of transmission, and is accompanied by profuse serous exudation of this portion of the conjunctiva. It produces great swelling of the lids, but the characteristic feature of it is that on eversion of the lids the fold of transmission is seen to be very much swollen. This is the form which has derived the name of *Schwellung's catarrh,* a name given it by the Germans.

A fourth variety of catarrhal conjunctivitis is that in which the serous exudation is very marked; it affects the conjunctiva of the eyeball as well as that of the lids. In these cases the conjunctiva is lifted up like a bag of fluid. The eyelid is so swollen that the patient is not able to open it; yet the exudation being deeply seated, there is very little if any discharge. This is known as the *œdematous* form of catarrhal conjunctivitis.

A fifth kind is that in which the more superficial layers of the conjunctiva are implicated. In these cases we are apt to have more discharge of a sero-flocculent character, a great many of the epithelial cells being lost. This is the form of conjunctivitis in which we see a fine granular appearance of the conjunctiva, as if it were sprinkled with sand. In milder forms this is probably due to swelling of the papillary layer; in severer forms the loss of epithelium in conjunction with swelling of the papillary layer are the principal lesions, and the palpebral conjunctiva has a red, velvety appearance. This form of catarrh, if neglected, is apt to become either chronic or, if irritation is added, it is apt to develop into a more serious disease, into a purulent ophthalmia.

In speaking of these five milder forms of conjunctival disease, I have mentioned as a cause of their development atmospheric changes. They may also be caused by abuse of the eyes, or by continued abuse of alcoholic beverages in a great many of these cases. Another factor has been impure air, and the impurity of the air may be due to obnoxious gases, as we find them in badly ventilated rooms, or to overcrowding as well as overheating of rooms. In many cases the influence of the air is merely to produce a more rapid evaporation of the tears and subsequent irritation of the eye; but in a great many the injurious admixtures of the air become absorbed by the moisture of the eye, and act as chemical irritants. Then the admixtures of the air causing conjunctival troubles may be of a mechanical nature. In walking through the crowded and not overcleanly streets of New York, one is surrounded by an atmosphere which is loaded with the sweepings of the streets, consisting of particles of horse manure, etc., which, if they get into the eye, are very apt to set up a conjunctivitis. This cause of inflammation has been so potent at times that only a few years ago New York was visited by a mild epidemic of conjunctival catarrh, which a great many authorities ascribe solely to the dirty condition of the streets. Dr. Loring published a paper in which he called attention to this fact several years ago. This mechanically irritating air is not confined, however, to New York or other large cities; it is also found in localities where the air is apt to be loaded with the dust of limestone or fine sand, and therefore we find that on the high plateaus of Nebraska, Arkansas, and other places, severe forms of conjunctival disease exist which are extremely obstinate to treatment. In fact, as long as the cause exists it is next to impossible to relieve the disease. I have had a number of patients coming from those localities who could not be cured of their conjunctival troubles as long as they remained there, but were cured here in New York.

Another mechanical cause existing in the air is snow. In very severe winters, when the snow is in the form of fine crystals driven by the wind into the face of travelers, a severe form of conjunctivitis develops, which is aggravated by the light reflected from the snow. This condition causes great distress to travelers in the arctic regions, by giving rise to irritation and affections of the cornea, and constitutes one of the forms of snow-blindness. It aggravates the ordinary form of snow-blindness to such an extent

that travelers have become completely blind from this affection. Simple snow-blindness, depending simply upon a superabundance of light, is not apt to lead to blindness. It is annoying, but it disappears as rapidly as it came, if the patient is kept in a dark room for a few days. It is in order to keep out the light and protect the eye from the particles of snow and ice floating in the air that the Esquimaux travel with spectacles made of wood, containing a little hole in the center, which answers the double purpose of keeping snow out of the eyes and of shutting out a superabundance of light.

The form of conjunctivitis to which men working at furnaces and firemen on steamers are exposed, is caused by a too rapid evaporation of the fluids of the eye.

It cannot be denied that another predisposing or exciting cause of conjunctivitis, is a lowered condition of the general system. Conjunctival diseases are, therefore, found, and are apt to become very serious, in old people or in persons who have been fasting during Lent. They are likewise apt to occur when persons have been living upon one kind of food for a length of time. Sailors and soldiers getting insufficient food, or food of the same kind for a long time, are more apt to develop conjunctival trouble. This is probably also the reason why in asylums, where the diet is nearly the same the year through, the children lose that power of resistance which is necessary to overcome injurious influences, and are therefore more apt to become the prey of conjunctival diseases. Overcrowding of institutions is to be considered one of the causes, as it leads to a vitiated condition of the atmosphere, and the greater and longer the crowding the greater will be the danger of development of conjunctival disease. This has been forcibly illustrated during the last examination of the asylums and industrial schools made in this city, which were made to ascertain the extent of conjunctival diseases in such institutions. I found that children who had been for one or two years in an institution of this kind suffered much less; perhaps only ten per cent. of them had conjunctival diseases; whereas the childen who had been there for five, six, or ten years, had suffered considerably, the number of cases rising in many instances as high as fifty and sixty per cent. Another illustration of this kind is, that children who are working in large, well ventilated rooms are not apt to have conjunctival diseases; while children working at something even less trying to the eye, but in a small room with a low ceiling, in which the temperature is high and the air bad, are apt to suffer from such troubles. In a room of the latter kind I found nearly two-thirds of the inmates suffering from chronic diseases of the conjunctiva—in fact, hardly a single healthy conjunctiva could be found among the 130 or 140 children thus employed.

The most potent etiological factor, however, is contagion, and it is a singular fact that in such cases there is apt to be a much severer form of conjunctivitis than if the disease has been brought on by atmospheric, hygienic, or mechanical causes. The severer forms of conjunctivitis, under which we understand malignant or purulent ophthalmia, blennorrhœa neonatorum, and gonorrhœal ophthalmia, as well as granular lids, are almost entirely due to contagion. The poison of purulent ophthalmia is derived from other cases of purulent ophthalmia. But this form of disease may also be due to an irritation of a previously existing simple catarrhal conjunctivitis. Another cause of purulency in the conjunctival affection is a greatly lowered condition of the general system. The same kind of disease which will set up a moderate amount of inflammation in a well-nourished person, may in a weak, and especially a lymphatic subject, cause a severe form of purulent ophthalmia.

In regard to the poison of blennorrhœa neonatorum, there is little doubt but what it is due to a specific organism which is found in the vaginal secretions of the mother, and which gets into the eye during the passage of the child through the vagina, or is brought into the eye by the injudicious and careless use of sponges or towels employed about the mother. This explains, perhaps, why blennorrhœa neonatorum is apt to be found after tedious labor, where the head of the child has been impacted in the vagina for some time before its delivery. Out of one hunhundred cases of blennorrhœa neonatorum which I have seen within the last few years, sixty occurred in primiparous mothers. As you well know, in these cases labor is apt to be more tedious, and that is where I think the principal trouble lies. In fifteen of the other cases forceps had to be used because the labor was tedious; and in only twenty-five cases had the labor been normal. In all of the cases the disease showed itself within one week after the birth of the child. However, we do meet with some cases in which a disease shows itself as late as the second or third week, as this inflammation differs, on account of its severity, from an ordinary cold; it is probable that in these cases the

causative agent is brought into the eye by the carelessness of the nurse, for it is a prevailing idea that an infection received at the time of birth may lie dormant one week, but not longer.

In order to avoid the danger of infection in confinement, it has been advised to disinfect and cleanse the vagina before the delivery of the child; but this is a difficult thing to do very thoroughly, because the secretion will form again as fast as removed, especially if the labor is a tedious one. A much more rational way of treatment has been to apply germicides to the conjunctiva of the child after its birth, when there is any suspicion of its having been infected by the secretions from the vagina. Inflammations of this kind are more apt to occur in lying-in asylums than in private practice, and I think the principal cause of this is not to be looked for in the condition of the hospital so much as in the condition of the patients, as the class of mothers who come to such institutions are much more apt to suffer from vaginal disease than mothers whom we meet in private practice. But there can be no doubt that the congregation of many women in one institution is a source of danger to a healthy vagina and to a healthy conjunctiva in the new-born.

This method of cleansing the eye after birth has been called Crede's method; it consists in dropping one or two drops of a ten-grain solution of nitrate of silver into the eye of the child immediately after it has been washed. The eye is washed with boric acid a few times after this. By this method the percentage of five or six or more has been reduced in many institutions to one-half or one-quarter of one per cent.

This is a disease which deserves the greatest attention on the part of the physician, because it has been proven by statistics that it is the most prolific source of blindness. Prof. Magnus, of Breslau, who published his magnificent essay on blindness and its prevention, which received several prizes in Europe, proves that nearly twenty per cent. of all blind persons are blind from blennorrhœa neonatorum.

The other form of contagious ophthalmia, gonorrhœal ophthalmia, is perhaps the most violent. Its etiology is as a rule, evident enough, but in a great many cases the existence of any discharge from the urethra or vagina is denied when an examination easily demonstrates the presence of a gleety or purulent discharge. The more recent and the more violent the disease of the urethra or vagina, the more serious the disease which develops in the eye. This disease destroys more than half of the eyes which are affected with it, and the contagious character of the discharge of the eye is such that the first and most important duty of the attending physician is to protect the other non-infected eye. A case of gonorrhœal ophthalmia is to be looked upon as half lost, and as important as the treatment is to the affected eye, equally important, or more so, is prevention of infection of the other eye. This disease is apt from the local infection to affect only one eye. The discharge may be conveyed by means of the finger, bandages, or direct transmission from the affected organ to the eye. Direct transmission may be through a syringe containing some of the discharge, or through small particles of the dry secretion being carried to the eye while dressing the organ, or by washing the eyes with urine, which is quite a popular remedy. We have many cases in which direct contact of the discharge from the diseased organ with the eye is established beyond a doubt. We have, in fact, cases of hard as well as soft chancre of the eye. Such cases, of course, are much more rare than those in which there is direct transmission of the purulent discharge of gonorrhœa to the eye.

The other form of contagious eye disease, namely, granular lids, is principally caused by contagion; but undoubtedly in many cases it is due to mal-treatment or neglect of an existing conjunctival disease. The mode of contagion depends, I think, in nearly all cases, upon direct contact of the discharge with the eye. I do not believe that the contagion can be carried through the air. There is no doubt that dry secretion may be carried in the air, but I do not think that a secretion which has become so dry as to be carried in the air is of much danger. In fact, we have no positive proof of contagion through the air. Several cases of this kind, so claimed, are in my mind unsatisfactorily proven. I believe contagion can not take place through the air, but only through direct contact. The mode of carrying the poison from one eye to the other is manifold. And although the secretion is not so violent in its nature, nor so abundant, in granular lids as it is in purulent ophthalmia, yet the apparently healthy appearance of the diseased eye may throw us off our guard and lead to greater exposure to contagion of this kind.

To mention a few of the modes of contagion, I have to speak, in the first place, of towels, especially of that abominable institution known as the roller-towel, which has

been used so much in asylums where forty, fifty, or more children use the same towel, whether they have granular lids or not. True, in a great many of these cases the existence of granular lids was not known; but even in cases in which the existence of the disease was evident, the ignorance or carelessness of the persons in charge has allowed transmission by means of towels to be one of the most frequent sources of contagion. As a carrier of the contagion, the house-fly plays an important *role,* especially in cases of young children who are not able to protect themselves against the visits of this little animal. Attracted by the sweetish odor of the discharge, it will settle upon the eyes of children affected with the disease, especially infants, and carry the contagion in its claws to the other eye or the eyes of sleeping infants.

Spectacles may be the carrier of the contagion. I remember the case of a young lady who could not explain satisfactorily how she came to have granular lids. Upon her return to school she mentioned that she had granular lids, whereupon one of her classmates said: "Why, that is the disease which I have been suffering from for the last six months." This classmate was near-sighted, and used glasses. My patient was also near-sighted, but had not used glasses, and whenever she wanted to see anything at a distance she was in the habit of borrowing the spectacles of her friend, and there is no doubt in my mind that this was the means of carrying the poison from the classmate's eye to my patient's eye.

Children with granular lids are very apt to rub the eyes, because the secretion as it begins to dry on the edge of the lids, causes an irritating, itching sensation. They will now play with other children, and from their hands transfer the poison to the hands of the other children, and these latter rubbing their eyes contract the disease. Handling objects which have been used by granular lids patients may be the means of carrying the contagion. A young lady who volunteered to teach children affected with granular lids, and who had been isolated from other children in a certain institution, was warned to be extremely careful with regard to using handkerchiefs, towels, or anything which belong to the children. She was well aware of the danger, and promised to be very careful. She handled nothing whatever, she said, that belonged to the children, left her cloaks outside, and in the class-room kept away from the children a distance of five or six feet. But upon examination of her eyes, fourteen days after she had taken office, it was found that she began to suffer from granular lids. Upon inquiry, I found that she had been taking the copy-books and slates of the children for correction, and in all probability she got the poison from the slates and books on her hands and then conveyed it to her eyes. A teacher of another section in the same institution was more careful; she simply walked into the class-room, did not touch anything belonging to the children, and for two or three months, during the duration of this epidemic, she was not affected by the disease. The atmosphere had evidently not been the carrier of the contagion in the first case.

The etiology of chronic blennorrhœa of the conjunctiva is always that of a previous acute attack of the conjunctiva or the extension of the inflammation from one of the appendages to the eye. Chronic blennorrhæa, which, as I said before, is characterized by excrescences and hyperplasia of the epithelium of the conjunctiva, which is lifted up sometimes in fine cauliflower-like excrescences, giving the conjunctiva a rough, velvety appearance, is as a rule the result of an acute blennorrhœal process. But it may also occur from extension of blennorrhœa of the tear-sac to the eye. In this way the disease may travel along the mucous membrane of the canaliculi until it comes to the conjunctiva of the eye; or the contagious element may be carried by the decomposing discharge of the tear-sac, which must now and then be squeezed out into the eye.

Another form of contagion has been claimed to be the common mold fungus. By a number of observations it has been shown that persons who sleep in badly ventilated rooms, in which the mold fungus develops, are apt to contract purulent ophthalmia or granular lids; but it is questionable whether these spores act simply as mechanical irritants, or whether they cause the development of similar formations in the conjunctiva, and thus give rise to the inflammation.

Conjunctivitis may also be caused by some drugs, such, for instance, as atropine, capsicum, or jequirity. Atropine conjunctivitis is not often met with; it is apt to occur in some persons after long-continued use of the drug. Capsicum or pepper are at times purposely thrown into the eye; they set up a smart and very painful conjunctivitis. Jequirity bean has been used in Brazil for some time for the cure of granular lids; it has gained quite a reputation for the cure of pannus. An infusion of jequirity beans, made of one bean to one ounce of water, is

brushed upon the conjunctiva of the lids once or repeatedly, until it sets up an inflammation. This inflammation is characterized by swelling of the lids and conjunctiva, and by the formation of a grayish membrane on the conjunctival surface. After the inflammation, which it caused, has subsided, the pannus is often considerably changed for the better, and the granulations are much smaller, or have disappeared entirely. The use of this new remedy is, however, at times followed by an inflammation of great severity and ulceration of the cornea; it should therefore be employed only by men thoroughly competent to meet these complications.

COMMUNICATIONS.

A CASE OF PSEUDO-EPILEPSY OF THE RETINA CAUSED BY HYPERMETROPIA.

BY F. C. RILEY, M. D.,

Of New York.

Presumably, true epilepsy of the retina never occurs independent of the epileptic state, although an epileptoid condition of this membrane may recur and at regularly varying intervals, and with such demonstrative effect as to be very misleading if not sufficient to cause a complete error of judgment. Undoubtedly during all epileptic convulsions the vessels of the retina become emptied and blanched as soon as the cerebral circulation, as a whole, is interfered with, and remain so during the interval of unconsciousness. Were we to use the ophthalmoscope at such time we would find this condition existing, and the usual power entirely in abeyance. That an epileptoid manifestation can occur entirely independent of a true epilepsy and be dependent upon a cause remote from any of a neurotic nature, the history and subsequent developments of the accompanying case fully demonstrate. The peculiar symptoms here presented are of interest not only to the specialist in ophthalmic surgery, but to every physician, for to any one such cases may present themselves, and an appreciation of the danger attending such phenomena at the beginning will enable him to alleviate to a considerable degree by his prognosis, the anxiety of the sufferer.

Mrs. W., aged twenty-five, consulted me in the summer of 1885, recounting the following symptoms: Has always possessed good eyesight until recently. Was quite ill about eight months previous to parturition, which illness was prolonged by excitement consequent upon the illness and death of a member of the family. Supposed, however, to have fully recovered from the effects of the foregoing previous to the manifestation of any ocular symptoms.

During a period of two months prior to my examination, she has experienced more or less constant pain in the supra-orbital region, and at times all about the region of the eyes, especially when reading or sewing, the same generally subsiding soon after laying aside the book or needle. For the past two or three weeks there was experienced a sensation of fogginess before the eyes at intervals varying from a few hours to two days, both when regarding near or distant objects —these attacks increasing in severity until the right eye was incapable of distinguishing light from darkness; in fact, the patient became absolutely blind in the right eye, which condition lasted from two to ten or fifteen minutes and then passed off, generally through varying stages to a perfect restoration of sight.

The inadvertent closing of the left eye brought to her mind a sudden realization that the blindness was confined exclusively to the right eye, and subsequent repetitions demonstrated conclusively that the left eye was never thus affected. Fearing organic disease of the right which might lead to permanent blindness naturally caused much uneasiness and perturbation of mind.

An examination of the eyes revealed the following:

Both eyes appear externally to be in normal condition. Insides dark; pupils regular and of same size; both respond perfectly and equally to light. O. D. V.=with $+\frac{1}{50}\frac{XX}{XX}$; O. S. V. = with $+\frac{1}{50}\frac{XX}{XX}$, showing a manifest hypermetropia of $\frac{1}{50}$. Slight insufficiency of internal rectus of right eye noticed when attention was concentrated upon a near object. Not having a set of prisms at hand the degree of adduction and abduction was not noted. With the ophthalmoscope the left eye was ascertained to be in a perfectly normal state. In the right eye was noticed slight engorgement of the veins, they being somewhat distended and tortuous, especially near the margin of the disc. Otherwise the fundus presented a perfectly normal appearance.

The patient had, therefore, all the symptoms of quinine epilepsy of the retina, with no other history of the disease and no abnormality to mention except the far-sightedness.

To prevent the return of the epileptical

manifestations, she was directed to abstain from all work necessitating the use of the eyes in a condition of active accommodation, and to use a pair of glasses ($+\frac{1}{60}$), representing almost the whole amount of her manifest hypermetropia.

The following day an attack occurred, which lasted but a moment, and did not produce blindness.

The second day a sense of fogginess of short duration was noticed, but no special inconvenience followed.

On the third day the glasses ($+\frac{1}{60}$) were received and immediately adopted, since when no recurrence of the epileptoid attacks have supervened, and with their use, in conjunction with a short course of faradization of the internal rectus muscle complete relief of all pain, inconvenience, and interference of vision has ensued. The lady recently informed me that she had not since experienced any untoward symptoms, and that with the aid of the glasses she is enabled to work steadily for hours at the finest kinds of needle-work, without experiencing the slightest sense of fatigue about the eyes.

The history of such cases demonstrate most conclusively the necessity of the use of correcting lenses in order to prevent the possibility of overtaxation of the accommodative power which generally occurs in the hypermetropic state unless glasses are worn.

This also brings to notice the diversity of manifestations that may supervene upon but a slight degree of refractive error.

DRAINAGE-TUBES IN SURGERY.

BY D. H. WOOD, M. D.,

Of Quincy, Mich.

Believing that there is no one article or device in the armamentarium of the surgeon that is more useful when applied intelligently, and in the right place, and more disastrous to the reputation of the surgeon, and the lives of his patients, when used in the wrong place, I desire to say a few words on the subject.

In deep suppurating wounds, especially where bone is involved, the drainage-tube is of great service. But what I wish to say will apply more especially to their use in the wrong place, viz., a serous cavity, particularly the pleural.

First let us see the effect of letting air into a pleural cavity. The lung in its physiological condition completely fills the cavity; the pleura-pulmonalis and the pleura-costalis are in direct contact with each other throughout their entire extent. Respiration is carried on or permitted by the expansion and contraction of the cavity. What expands the cavity? Does the inflation of the lung expand it? Or does the expansion of the cavity facilitate, or cause the lung to inflate, or vice versa? I think it is clear to all that the latter is in the main correct.

That being the case, we will now suppose a drainage-tube to be adjusted, and at each respiratory effort or expansion of the chest, air is freely admitted through the tube into the pleural cavity. What follows? The function of the lung is compromised, its air-cells collapse from atmospheric pressure from without, and as time goes on the lung ceases to be a respiratory organ, becomes *collapsed* and *carnified*. But, says some reader, how are you going to treat empyema without the use of the drainage-tube?

Early in my professional career it was my fortune to make an autopsy where the patient had died of chronic empyema. There were five fistulæ from which, I was told, pus had flowed for a period of ten months. Without going into further details of the case, I will give the lesson I there learned.

I determined to investigate nature's mode of drainage. I first attempted to pass my probe through one of the openings into the cavity, and failed. I next tried my blow-pipe, and to my utter astonishment I could not force a particle of air into the cavity. I then introduced the nozzle of my blow-pipe into the other end of the sinus, and tried again, with great success—I not only forced air through readily, but with it came quite a shower of pus into my assistant's face, who was eagerly watching the external opening. I said to myself, I have dislodged all obstruction, and introduced my blow-pipe into the external sinus again (very confident of success this time), but despite all my efforts, I could not prevail on that little drainage-tube to convey air from without inward, but the reverse with great ease. This to me was a strange thing, and I determined to search further and if possible discover the mystery. I noticed more carefully the external opening, and my attention was directed to three small pouting lobes of granulations surrounding it. These little sentinels were as completely adjusted to the closure of the sinus as are the tricuspid valves of a normal heart. I then dissected the little tube out of its tortuous bed, and after measuring its length, which was $4\frac{3}{4}$ inches, I again tried my blow-pipe, with like results as before. I then took my knife and laid it

open from end to end. I now discovered "flaps" or "folds" or "pockets"—call them what you may, I choose to call them *valves*—that bid defiance to the *ingress* of air, but afforded little or *no* obstruction to the *egress* of pus. This was a valuable lesson to me, and as I believe, has been more valuable to my patients than myself. I have since that time treated many cases of pleuritic effusion, both purulent and non-purulent, ever remembering the early lesson as told above, and I have never had to pass my patient over to the undertaker.

Surgeons should remember that *God* never uses a drainage-tube without a *valve*.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

Service of Dr. J. M. Da Costa.

Case of Walking Typhoid Fever, with Intestinal Perforation and Uræmic Symptoms: Death.

The patient, a man of thirty years, was a Norwegian, and could not speak English well. He gave no history of having been ill prior to five days before admission, when he was seized with a chill. This was followed by persistent vomiting, successive chills, prostration, and abdominal pain. In fact, he complained of pain all over his body. Bowels were regular and rather loose. He was in the hospital only twenty-four hours, during which time he passed no urine. On admission, his temperature was 103°, pulse 32, respiration 38. The tongue was coated and breath foul. Intellect seemed clear. He was somewhat emaciated. Vomited dark-greenish matter very frequently.

Physical examination revealed but little. Heart-sounds weak. Lungs negative. Abdomen tender on percussion; not distended. Bladder seemed empty.

Treatment consisted of morphia, hypodermically, p. r. n., and 15 gtts. tincture digitalis every third hour.

Next morning the patient seemed much weaker—almost comatose. Temperature slightly below normal (98°); pulse 140; respiration 30. Vomiting persisted. He was somewhat cyanosed. His pupils were dilated and his muscles twitched as if in threatened convulsion.

As he had passed no urine since admission to the hospital, the catheter was used, and only five ounces of urine obtained.

The condition found upon analysis and microscopic examination was as follows:

Specific gravity 1027, reaction acid, and containing a trace of albumen. A few granular casts, a few red blood disks, epithelium, and uric acid crystals.

Dry cups were freely applied over the loins, and cocaine in one-half-grain doses ordered every third hour. A steam-bath was also administered with the hope of exciting the skin to activity. He rapidly weakened, and died at about 11:30 after what seemed like a slight convulsion.

The autopsy was made five hours after death. Body slightly emaciated. Rigor mortis well marked. The muscles are dark colored and soft. The heart shows slight but distinct hypertrophy of the left ventricle, and some atheroma of the aorta. The valves of the heart are in good condition.

Lungs are crepitant throughout; no evidence of tubercle. They are congested posteriorly.

Abdomen.—On opening the peritoneum, it is found to be injected and to contain a purulent fluid having a strong fecal odor.

Stomach shows evidences of chronic gastritis of long standing, the mucous membrane being markedly mamillated and in some parts ecchymosed.

Small intestines.—The ilium contains several small ulcers, very deep, and occupying the site of Peyer's patches. One of these ulcers has *perforated*.

Large Intestines.—Mucous membrane is swollen, and there is some ulceration about the head of the colon. Mesenteric glands are enlarged.

Liver is congested and softened.

Spleen is about normal in size, dark colored and firm.

Kidneys are rather small (weighing about 2½ ounces). Their capsules are not adherent. The relation between cortical and medullary substances is natural. There is some congestion, but otherwise the kidneys are apparently healthy.

Now this man died of uræmia, with symptoms of perforation of the bowel. This is illustrative of *walking typhoid fever*. The patient not being aware of his condition, and complaining only for six days, whereas he was probably ill for a length of time. It was not, in fact, till the post-mortem revealed the lesion in the intestine that his disease was known to any one.

The interesting question is, why did he have uræmic symptoms, since the kidneys were *not* diseased, but only congested? During 24 hours the kidneys were only able to secrete five ounces of urine. What induced

this uræmia? As I repeat, there was some hypertrophy of the heart and congestion of the kidneys, but no pre-existing disease of the organs to account for uræmia. *Why then did it occur?* is the diagnostic point of greatest interest. The typhoid lesion must have been marked to have produced perforation.

Now the shock produced by perforation was so great as to cause suppression of urine and the consequent *uræmia*. The case is instructive as showing how a patient with intestinal ulceration may walk about till perforation of the bowel occurs, having no symptom of typhoid fever except the often unreliable one—abdominal tenderness.

Medical Societies.

GYNÆCOLOGICAL AND OBSTETRICAL SOCIETY OF BALTIMORE.

Regular meeting, held October 12, 1886.

DISCUSSION ON DR. ASHBY'S PAPER.

(*See page* 645.)

Dr. B. B. Browne said he had reported about two years ago two cases in which he had used cocaine in dilation of the cervical canal. Since then it was his habit, in office practice, when slight dilatation was required preparatory to intra-uterine applications or curretting, to first apply a 4 per cent. solution of muriate of cocaine to the canal. When full dilatation is required he prefers full anæsthesia, but he has used the cocaine successfully in two such cases. In two cases of acute anteflexion he injected 20 drops of a 40 per cent. solution into the uterine tissue near the point of flexion. In a few minutes he was able to pass a sound without pain, and also to apply cotton saturated with cocaine. He thinks that by its effect on the circulation it tends decidedly to prevent the occurrence of cellulitis after local interference. He applies it to the cervical canal on cotton wrapped around a probe.

Dr. L. E. Neale said he would like to ask for information if any gentlemen present had had experience with the use of cocaine by hypodermic injection. He thought the method of administration of great importance in judging the effects of the drug.

Dr. W. T. Howard said that so far as he knew, Dr. W. M. Polk, of New York, was the first, about two years ago, to use the hydrochlorate of cocaine as a local anæsthetic in the operation of trachelorrhaphy. He used it in two cases. Having previously douched the vagina with warm water, the cervix, the patulous cervical canal, and the vaginal walls adjoining the cervix were washed with castile soap; this, in turn, was washed off, and the surface carefully dried. Then, a four per cent. solution of cocaine was thoroughly painted, with a camel's-hair brush, over the cervix, in the canal, and over the adjacent vaginal wall. This was done three times, allowing an interval of three minutes between each application. In one case, the operation lasted forty minutes, and there was no complaint of pain till the last ten minutes, when an uncomfortable soreness was felt. Soon after the publication of these cases, Dr. Howard had operated on a number of cases of lacerated cervix, pursuing essentially the plan used by Dr. Polk, and with similar results. Dr. Howard had noticed, however, that in passing the needles through the lips of the cervix, in the usual way, with the silk loop and silver wire attached, the patients invariably complained of pain, more or less acute, in different cases. Hence, in all cases in which the laceration occurred in a large hyperplastic cervix, demanding the removal of a certain amount of parenchymatous cervical tissue, to prevent the sutures cutting out and thus hinder accurate union, Dr. H. much preferred that the patient should be put under the influence of ether, in order to insure a painless operation. Dr. H. doubted whether it was advisable to inject a solution of cocaine, with the hypodermic needle, into the cervical parenchyma, as the tissues are too dense, in most cases, to allow of a rapid diffusion of the anæsthetic influence of cocaine. He had seen, however, in a recent number of the *Brit. Med. Jour.*, a report of the removal of hemorrhoids in two cases, which were rendered painless by injecting five drops of a ten per cent. solution of the hydrochlorate of cocaine, by means of a hypodermic syringe, into each side of the base of the hemorrhoid. After the operation, a morphine suppository was inserted into the rectum, and, subsequently, not the slightest pain was experienced.

Dr. H. had now under care a married lady, aged twenty-five years, who suffered severely from from dysmenorrhœa. She had an anteflexion of the vaginal portion of the cervix, with acute angular flexure at the posterior vaginal junction, and stenosis at the os internum. He determined to dilate the cervical canal with his dilatorium; but as the patient had grave organic trouble at both the aortic and mitral orifices, he thought that the administration even of ether was unadvisable. He, therefore, had applied by means of a mop made of absorbent

cotton, a twenty per cent. solution of the hydrochlorate of cocaine, as thoroughly as possible, to the cervical canal twice, at intervals of five minutes, and keeping the cotton mop in the canal for five minutes each time. Then, he carefully dilated the cervical canal, including the os internum, occupying fifteen minutes in dilating to three-fourths of an inch. This lady had great fortitude and strength of character; and, while she did not utter a complaint, when the operation was over the shock was quite severe, and demanded a hypodermic of gr. ¼ of morphine. The pain induced by the operation was severe. The next day, in a similar case, Dr. H. operated in the same way, and with the same precautions. The patient was extremely nervous, anxious, and apprehensive, but had no heart trouble. She experienced little or no pain during the entire operation, although the dilatation was much greater, *i. e.*, one and one-fourth inches. These two cases demonstrate that the amount of pain depends much upon the peculiarities of the patient; and it is well known that the normal sensibility of the female genitalia is a constantly varying factor in different persons.

Dr. B. B. Browne referred to his previous remarks, in which he stated that he had injected twenty drops of a four per cent. solution into the uterine tissue, and there had been almost no suffering during the process of dilatation.

In one case of lacerated cervix he had painted the solution over the cervix, and had also injected it into both lips. In this case there was perfect freedom from pain, but it was impossible to say how much of this effect was due to the injected cocaine, and how much to that applied upon the surface. He would recommend in cervix operations that it be used in both ways, on the surface and hypodermically.

Dr. W. P. Chunn had used cocaine once, in a bilateral laceration of the cervix. He painted it over the cervix, then injected it into the anterior lip, and after denuding that, injected into the posterior lip and finished the operation. The patient seemed to suffer little or no pain.

Dr. W. E. Moseley had had some experience in the use of cocaine. He had always used a four per cent. solution, and had always applied it by painting the surface to be operated upon freely from three to five times, at intervals of three minutes. He had done several cervix operations, and found it to answer very well when there was but little cicatricial tissue to be removed from the angles. There was little or no sign of suffering while the surfaces were being denuded; in most cases when the needles were passed the patient showed signs of feeling decided pain, requiring reapplication of cocaine. In one case of operation high up in the cervical canal, the patient said she felt no pain throughout the operation and that she would not have known when the sutures were introduced except for a remark that was made. She did feel the dragging upon the uterus when the needles were passed. Another patient said that the most suffering she had was when the shank of the scissors pinched a bit of the tissues about the vulva.

He had also very reluctantly, and at the earnest solicitatation of the patient, done Dr. Emmet's new perineum operation under the same anæsthetic, but he would not be willing to do so again. Denudation was accomplished without any marked trouble, but the introduction and tightening of the sutures caused very decided suffering.

He greatly preferred full anæsthesia for either the cervix or perineum operation.

In no case had he been able to *demonstrate* that cocaine interfered with prompt union of the denuded surfaces, although he was inclined to think that it did to some slight extent.

Dr. B. B. Browne referred to a case of septicæmia in his practice, in which there was some nausea, vomiting and hiccough, in which he gave ten drops of a 4 per cent. solution of cocaine. The symptoms were very promptly relieved, and the relief lasted for twelve hours, when he repeated the dose. He had given it also with good result in the nausea and vomiting in pregnancy.

Dr. H. P. C. Wilson said that any remarks that he could make would be very much of a repetition of what had already been said, as his experience with cocaine had been much the same as that of the other gentlemen who had spoken.

He had used cocaine when operating in five cases of lacerated cervix, when the patients feared ether or chloroform. By thoroughly painting the surface with a 5 per cent. solution, and introducing it within the cervical canal, he could denude the parts without pain to the patient. Some of the sutures could also be passed without pain, but the deeper and last sutures are usually attended with suffering sufficient to require cessation of the operation and re-application of the cocaine. The union of the parts after this agent was just as prompt and complete as without it.

But even when this operation could be done without pain under cocaine, if it was at

all tedious, the patient was apt to become nervous and more or less restless, and move at a critical moment of cutting or passing a needle, and thus embarrass the surgeon; and hence he preferred the general and profound anæsthesia of ether or chloroform, to the local anæsthesia of cocaine.

He had never used this remedy hypodermically, but this method, in conjunction with its superficial use, would probably deaden the sensibility of the parts more completely.

He had heard of the nausea and vomiting of pregnancy being promptly checked by applying a solution of cocaine to the surface of the cervix uteri, and up the cervical canal, so as not to pass the internal os. The suggestion looked reasonable, and he would try it in the first case that presented.

Dr. T. A. Ashby, in closing the discussion, remarked that there were only two or three points to which he wished to direct attention. In regard to the point raised by Dr. Howard, with reference to the different degrees of sensibility to pain in different women, he fully coincided with these views and thought that this explanation satisfactorily accounted for the failure of cocaine to affect all cases alike. He had observed this fact, and was convinced that the anæsthetic properties of cocaine were not of equal extent and value in all cases.

In reply to the inquiry raised by Dr. Neale in regard to the hypodermic administration of cocaine, Dr. Ashby referred to the valuable experiments and observations of Corning of New York, who was the first worker in this field to demonstrate the great value of cocaine injected subcutaneously. Dr. Corning has shown that where the tissues are constricted in such a manner as to prevent rapid absorption of the injected solution, profound local anæsthesia is the result. The literature of medicine is now filled with the recital of caaes showing the wide application of this method and its great value. The removal of necrosed bone, amputation of limbs, laparotomy, circumcision, closure of hare-lip and similar procedures have been painlessly performed under cocaine injections, employed after the method inaugurated by Dr. Corning. Dr. Ashby thought that a practical difficulty would be met with in injecting cocaine into the cervix uteri and perineum, on account of the inability of the operator to prevent rapid absorption of the solution, owing to the fact that the cervix uteri and perineal tissues could be constricted only with the greatest difficulty in a few exceptional cases. He believed that Dr. Corning's method was less applicable in female surgery than in surgical procedures elsewhere.

Dr. L. E. Neale thought the ecraseur carrying a catgut loop, shown by Dr. Erich at a previous meeting of the Society, would answer the purpose of constricting the cervix very well. After drawing the uterus down in the vagina, he saw no difficulty whatever in throwing the loop around and constricting the cervix at any desired height; the higher above the vaginal junction, of course, the more vaginal tissue included in the constriction. It was not at all necessary for the use of this instrument to have an elongated cervix.

Dr. B. B. Browne thought that when constriction was used together with application of cocaine, we must credit the constriction with a very considerable anæsthetic effect, and he believed the more thorough anæsthesia was due to this rather than any checking of the absorption of the cocaine into general circulation. He referred to a case in which a friend had operated for phymosis, the only anæsthesia used being constriction of the penis. In this case the patient suffered no pain.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Thursday, November 4, 1886.

The President, B. F. Baer, M. D., in the chair.

Dr. Joseph Price exhibited specimens from two cases of

Pyosalpinx.

Dr. M. Price exhibited specimens from one case. All of these were of gonorrhœal origin. Those by Dr. J. Price were removed from prostitutes. That exhibited by Dr. M. Price was from a married woman who had been infected by her husband. The tubal disease manifested itself soon after childbirth. The menstrual period had always been very painful, and had kept her in bed from eight to ten days.

Dr. Howard A. Kelly exhibited a

Sarcoma

as large as a man's head, which he had removed from the anterior abdominal wall. It had its origin at the transverse tendinous band of the right rectus muscle, just below the umbilicus. The mass was about eight eight inches by ten, and hung pendulous under the greatly thickened skin of the right umbilical, inguinal, and iliac regions. The great point of difficulty was in determining before operation whether the mass did not

spring from a small hernia slipped through the umbilical ring, which was greatly drawn out on one side over the tumor, and deep in which the fibre-like cords of the attachment could be felt. The tumor was very vascular, but was readily removed, and the patient made a perfect non-febrile recovery.

Dr. Kelly also exhibited a specimen upon which he desired a report by the Microscopical Committee. The case was one of great interest,

An Ovarian Pregnancy,

upon which Dr. Kelly had operated within the past twelve hours.

The patient, a German woman, who had had one child by forceps delivery, two years ago, in Germany, had since been regular in her menstruation until October, when she went two weeks over time, and was then roused in the night by sudden violent pain in the right leg and groin, extending obliquely down the right ovarian region. With the pain came a profuse uterine flow, which lasted for two weeks with intermissions. From excellent health, she was immediately prostrated and became miserable, with elevated temperature and quick pulse. She had no organic disease, but a small tumor at the extremity of the right fallopian tube. The tumor was about two and a half or three inches in diameter, softish, not sensitive, freely movable in the pelvis. In front of this a sharply defined round ligament could be traced out to the brim of the pelvis, and above this the flatter cord of the fallopian tube could be felt. The ureters were enlarged, as Sänger has noticed, and the speaker has frequently verified in pregnancy. The uterus was of a size approaching two months' pregnancy, and the cervix was remarkably soft for the early stage of pregnancy. Dr. Kelly sent invitations to Drs. R. P. Harris, J. G. Allen, Freemann, John and Frank Haynes, Jos. Hoffman, Geo. Horn, and Wm. Ferguson, to be present at an abdominal section for extra-uterine pregnancy, and in their presence the operation was carried out. (The patient, up to date of publication, has made uninterrupted progress toward recovery.) Dr. Kelly exhibited a chorionic membrane from a uterus, with a four weeks' fœtus attached.

Dr. Beates remarked that the lining membrane of the cyst was easily separated from the wall, and he thought the specimen was most probably a parovarian cyst.

Dr. Jos. Price thinks the cyst could be entirely shelled out. He thought it had none of the characteristics of a tubal pregnancy.

Dr. Kelly, in closing the discussion, demonstrated in the extra-uterine and in the uterine specimens an identical membrane which could be detached, and which was the amnion. He demonstrated ovarian tissue completely surrounding the cyst, thus proving that it was not parovarin in its origin. The lining membrane underlying the apparent amniotic membrane is a soft tissue never seen in an ovarian cyst. The specimen was referred to a committee.

Dr. Longaker exhibited a fibro-myomatous substance which had been expelled from a uterus twenty-three days after normal labor. The placenta came away entire; there was a post-partum hemorrhage on the second day. In the third week a rise of temperature occurred. The temperature became normal after the expulsion of this mass.

Dr. Kelly said that judged by the macroscopic appearance of the specimen alone, and with great certainty in view of the history, this flat elongate mass with one semi-circular rounded edge, and with long shreds hanging to it, was a portion of a retained placenta. A question is by this brought up upon which it is of the utmost importance that every member of this Society should have positive convictions, and that our practice should be uniform, and that is—What shall be done in the case of a puerperal woman who has an elevated temperature and a foul-smelling discharge from the vagina? Where other manifest cause was absent, every such patient should be placed in a convenient posture and the uterus thoroughly gone over with a dull curette, followed by a swabbing with an antiseptic solution. Thousands of women are to-day suffering from neglect of this simple precaution of removing stinking shreds of decidua and pieces of placenta, which remaining have caused subinvolution, chronic endometritis and cellulitis lingering for years, or even a more acute and rapidly fatal septic process. Dr. Kelly prefers the lateral semi-prone position for convenience of exposure and manipulation, considering the objections which nave been urged against this as purely theoretical.

Dr. Baer would prefer the patient on her back for scraping or washing out the uterus after labor, using tincture of iodine or bichloride solution.

Dr. Beates has made it a rule whenever the temperature rises after labor to introduce the finger or curette into the uterus and remove any adherent masses.

Dr. Longaker, in closing the discussion, said that he had not the slightest doubt that the specimen had been a fibroid tumor buried

in the tissues of the lower portion of the uterus; the contraction and involution of the uterus cut off its supply of blood and partially enucleated it. Time was required for this process. The rise of temperature did not excite immediate suspicion, as the case was a hospital one and the wards were crowded at the time.

Dr. Beates, on behalf of the committee, stated that the microscopic examination of the "ovarian fibroid" presented by Dr. Baer at the October meeting showed it to be a neoplasm developed from the epithelium of the ovary; it was a true scirrhus, with nothing ovarian about it except its origin.

Hysterorrhaphy.

Dr. Howard A. Kelly read a paper, written for the Society in the spring of this year, upon a new operation which he called hysterorraphy, or the *suspension by suture* of a *viciously-posed uterus;* that is, an organ prolapsed or retroflexed, which it is impossible to relieve by any line of treatment applied per vaginam.

The speaker first applied this method, April 25, 1885, upon a patient who had been under the care of several other specialists, and under his own care for nearly three years. The uterus had lain acutely retroflexed, with a large soggy fundus, in Douglass's pouch below the level of the cervix. Months of rest in bed, combined with careful packs and counter-irritation, and for a long time applications to the endometrium, failed to cure the flexion even temporarily.

The patient had been operated upon a year previously, removing a very tender ovary per vaginam. On this occasion the left tube and ovary were removed, and as the right tube could not be felt, it was concluded it had atrophied. The uterus was then raised and a sharp band of cicatrix-like tissue felt half encircling it in the angle of flexion, when the futility of any attempt to relieve the condition from the outside was at once evident.

Silk sutures were passed through the left horn of the uterus and the body suspended from the anterior abdominal wall, about one and a half inches above the pubis to the left of the incision. The suspensory sutures were passed between two ligatures encircling the horn and the base of the pedicle, to avoid the dangers of tearing out and of bleeding.

The uterus thus suspended remained in place one year, when the right tube enlarged to a hydro-salpinx, and just before operation for its removal, dragged the fundus over.

Dr. Kelly urged that in future both cornua be utilized, and attached between one and a half and two inches above the pubis, to allow room for free expansion of the bladder; and again, that while in most instances the disease will have been of such long standing as to involve chronic incurable disease of the appendages, necessitating their removal, yet in some cases the good effects of drainage of these latter, which are raised with the body, should be tried. The operation is to be urged where the long retroflexed infiltrated uterus is unable to stand up straight alone after removing diseased ovaries and tubes, and if adhesions bind the fundus down they should be carefully severed. He also insisted that the operation for shortening the round ligaments was not admissible for retroflexion alone, as owing to enormous mechanical disadvantage the slightest degree of relaxation would allow a reproduction of the deformity.

While in simple prolapsus, if a suprapubic operation of any sort were ever necessary, which the speaker doubted, he would prefer a simple, aseptically made, abdominal incision and direct support by attaching the fundus to the anterior abdominal wall, in an operation which has a doubtful and possibly a high rate of mortality, and of which the ratio of success is even more problematical.

The operation has been devised and performed independently by a number of prominent gynecologists in various parts of the world, among whom are Koeberle; Bardenheuer, of Cologne; Hennig, of Leipzig; Czerny, of Heidelberg; a surgeon in the north of Italy; and Lawson Tait; probably Keith; and two cases not published, which Dr. Sänger, of Leipzig, kindly gave the writer during the past snmmer. (This paper will appear in full in the *Medical News.*)

Dr. Drysdale remarked that he had performed a second operation upon a lady upon whom eighteen years previously Dr. Atlee had performed ovariotomy for the removal of an ovarian tumor; at the first operation the uterus was found prolapsed. In this operation Dr. Atlee had used the clamp to secure the pedicle, and at the second operation the uterus was found attached to the original wound. The prolapse had been effectually cured. He thinks both cornua should be secured to the abdominal wall. He had never met with a case of retroversion that could not be relieved by pessary after curing the accompanying endometritis. Many years ago, a lady who had been for eight years under the care of H. L. Hodge for retroversion, and in whom the presence of a pessary excited such expulsive efforts

that it could only be worn a week at a time, came under the care of Dr. Drysdale; he treated the endometritis first, and when it was cured a pessary could be retained, and complete relief was secured.

Dr. Jos. Price remarked that Tait considers it dangerous to stitch the fundus uteri to the abdominal wound, and has abandoned it. In some operations he introduces sutures to draw the uterus high up, that he may more readily remove the tube close to the cornua.

Dr. Baer thought it seemed the most natural method to stitch the fundus to the abdominal wound. He asked for what reason Dr. Tait considered it dangerous. He thought the field of Dr. Kelly's operation would be small, as when the endometritis was cured, a pessary or other support would relieve the retroversion or flexion. After laparotomy or removal of the uterine appendages, it might be advisable in some cases to draw the uterus up. He has had experience with such a procedure. He does not like the Alexander operation; he considers it unscientific, and in many cases it has failed to cure the displacement.

Dr. Longaker feared that granting that anteversion could be secured by Dr. Kelly's method, the bladder would not be allowed to expand, a fixed anteversion would itself be pathological. He would hesitate to stitch the fundus to the abdominal wall, even after removal of the appendages. Retro-flexion does not necessarily produce discomfort, as some cases have no symptoms to call attention to the condition.

Dr. Harris recalled the case of Mrs. Reybold, whose uterus was suspended for fifty years. She died at eighty. The senile organ was drawn out into a tongue-shape; the uterine attachment was one and a half by three-fourths inches at time of death; the uterus was four and a half inches long, and the vagina was lengthened and cord-like. There had always been a tender spot in the cicatrix, probably from tension.

Dr. Kelly stated in reply that he considered the main points which had been raised had been already answered in the paper. He considers these cases *rare*, and by no means recommends a resort to section and suspension without first trying every other known expedient likely to relieve, and then only in those cases in which the local disorder causes such pain or disability as to render life a burden. He considers the operation established, however, in those cases in which after removal of the appendages the flexed organ fails to remain upright when lifted into position. An occasional resort to hysterorraphy will not affect the table of recoveries from operation, but will affect the list of patients *cured*, which is not always made so prominent after abdominal section.

W. H. H. Githens, *Secretary.*

Editorial Department.

Periscope.

A Peculiar Case of Pregnancy.

Before the Brooklyn Pathological Society, Dr. Walter J. Corcoran related the following history:

In the last of August, 1885, Mrs. V. applied at St. Mary's Hospital for the repair of a lacerated cervix. Her last child had been born two years before, after a tedious labor, terminated by the forceps. Since that time she had been under constant local treatment for "ulceration of the womb," etc., by several physicians, the last of whom recognized the true condition and sent her to the hospital for operation. Since the birth of her child menstruation had occurred only at intervals of four and five months, the last time being in June. This was the only noteworthy symptom connected with the case. Examination showed an extensive bilateral laceration, the uterus large and soft, and five inches in depth. She was put on the usual preparatory treatment.

About the middle of September the laceration was closed by Dr. Byrne. During the operation it was noticed that the tissues were unusually soft, and that there was a very free oozing from the raw surfaces, though no large vessels were cut. The period of repair was normal, and in two weeks the sutures were removed and union was found to be perfect. When the sound was introduced it passed five inches. Thinking that it might possibly have passed into a dilated tube, the sound was well curved and rotated in the cavity with the same result. To reduce the size of the uterus, which was supposed to be in a condition of exaggerated subinvolution,

a paste composed of iodine, iodide of potassium, ergotin, and glycerin, was ordered to be introduced into the uterine cavity twice a week by means of Dr. Byrne's intra-uterine applicator, and fifteen minims of ergot were given three times a day. This treatment was continued about four weeks, with no result whatever. After each introduction of the paste, membranous shreds came away, as is the usual result. There was no colic, no ergotism. In the last week in October, after the accustomed application had been made, the patient calmly announced that she had milk in her breasts. This statement first aroused the almost impossible suspicion that the enlargement of the uterus was due to pregnancy, even despite the manipulations it had undergone. A careful examination was then made to settle this point, but none of the positive signs of pregnancy could be found. The sound *had* passed (it was not passed again) in the median line to a depth of over five inches. The patient's abdominal walls were very thick and very lax, so that a large fold could be grasped in the hand. The uterine tumor was all in the right side, not extending, or but very little, across the median line (although the sound passed in the centre) and reaching half way to the umbilicus. Ballottement, rhythmic contractions, placental bruit, fœtal heart-sounds, were all absent, or could not be found. There had been amenorrhœa since June, but during the previous two years she had menstruated only at intervals of four and five months. There was no nausea or other sympathetic disturbance. There was a slight areola, also a secretion in the breasts. If she was pregnant, she was in the beginning of the fifth month. She had been subject to constant local treatment. The sound had been occasionally used to determine the depth of the uterus. In the third month a bilateral laceration of the cervix had been repaired, and during this operation there was a large loss of blood and the uterus was drawn down by a spreading double tenaculum opening in the cervical canal. A strongly-curved sound had been freely rotated in the cavity, not a drop of blood following its use. A compound which caused exfoliation of the lining membrane had been introduced a number of times, and she had taken fifteen minims of ergot three times a day for nearly a month. Yet there was a strong suspicion of pregnancy, possiby extra-uterine, or in one horn of a double uterus.

No diagnosis was made, and developments were awaited. It was needless to say that further medication ceased. Soon after this the patient reported that as soon as she stopped her medicine (ergot) the movements, which before were very ill-defined, became much stronger. The uterine tumor became gradually more central, and about the middle of November the fœtal heart-sounds were heard. Ballottement was obtained, not through the cervix, but anteriorly through the body of the uterus, and the fœtus was undoubtedly in the uterus. Dr. Byrne saw the patient, and confirmed this opinion. On January 4, during a severe coughing spell, the funis was projected from the vulva, and although it was replaced and retained within the uterus, she was delivered the following night of a still-born child of about seven and a half months' development. The epidermis was slightly macerated, and peeled off the scrotum and anterior aspect of the thighs. The placenta was attached to the right side, and was exceedingly soft and friable.

Dr. A. H. P. Leuf remarked that he had had a somewhat similar experience, which was too good to keep. Some four months ago he had been called to see a woman of forty-five years, presumably at the menopause for nearly two years, as indicated by the irregular menstruation during that time, and its total cessation for four or five months. She thought she was pregnant, but was uncertain. She was the mother of seven or eight children. The usual signs of her other pregnancies were absent, except lacking menstrual discharges and some abdominal enlargement. The tumefaction was on the right side, just above the brim of the pelvis. It was a little sensitive on pressure, and occasionally caused pain spontaneously. A careful examination of the uterus admitted of a positive demonstration, even to her husband, who was present, that uterine pregnancy was utterly impossible. The probe entered the uterus along the uterine wall to the fundus, and was withdrawn along the posterior wall. It was again pressed up on one side, swept around, and brought back on the other. A bimanual examination demonstrated the uterus to be freely movable, and only slightly elongated. The possibility of an intra-uterine pregnancy was most positively denied, and a fear expressed that the abdominal tumor might be an extra-uterine pregnancy. She was not seen again, but her brother reported that she continued to suffer occasional pain; there was still no appearance of menses, and the patient was troubled with mental uneasiness about her future condition. The brother was urged to send her around for re-examination. While the

speaker was making a professional visit to the oldest child of this woman, and upon her being questioned as to her present condition, she stepped over to a bed, drew aside a cover, and exhibited a two weeks' old baby. She was not again examined. The baby was one she had been normally delivered of by a midwife. In all probability the membranes were firmly attached to the uterine walls to within the distance from the os to which the probe had penetrated. An anterior uterine fibroid might have led to the error following the bimanual examination. These cases simply taught us the ease with which such errors might at times be made, and yet not the least blame attach to the physician.

Medical Women and their Husbands.

The N. Y. Med. Med. Jour. says:

In a recent number of *Lyon Medical*, we find an account, quoted from the *Petit Marsellais*, of a domestic contention between a lady practitioner of medicine and her husband, which has led to proceedings before one of the courts. The action turns upon the question of a husband's legal right to open and read the letters received by his wife. The husband in this case prays the court to affirm his right to do so, and the wife asks that he be restrained from taking such a liberty. The points as stated by the parties to the suit, show a sort of hand-to-hand conflict grievous to contemplate from the domestic point of view, but one that, it is not difficult to imagine, may readily arise between other medical women and their husbands, and one that is therefore of interest to a rapidly-increasing section of the profession.

The lady states that it is a matter of every-day experience for her to receive written communications from her patients, and that in many instances they are of such a nature that professional secrecy is violated if they are read by her husband, who, she says, consented to her becoming a physician, and should have taken the consequences into account. She could no more think, she adds, of taking him into her confidence in such matters than of allowing him to witness her private examinations of patients. The husband replies that he would resign himself if it were only from women that the letters came, but says that she gets them from men also. She then asks him if she ever agreed to restrict her practice to women. "No," he mildly answers, "but what about propriety and modesty?" "Everything," the wife retorts, "vanishes in the interest of humanity and science. I have dissected male as well as female subjects. I am *blasée* as regards your sex, as I am indifferent to the other. To me man is nothing more than a subject of observation." "That," says the husband, "I can not admit. Since you pretend to love me, or to have loved me, it is evident that your studies have not made you indifferent. I have reason to believe that you are not incapable of sentiment. I fear that your imagination will get the better of your science, and that some new, unknown man will set your heart or your nerves quivering as the result of confidences and visits." "You would forbid my practicing my profession," says she. "No," says he, "I would only take part in it with you to a reasonable extent. I ask not to practice medicine, but I must watch over you as I vowed before the civil magistrate. I owe you aid and protection. How can I protect you if I know not the dangers that threaten you? I will tell nobody what I may read, but I insist on reading everything. Since many women write a masculine hand, just as many men write a feminine hand, I can tell the one from the other only by breaking the seal of every missive, and leaving none unexamined."

In his heart, this solicitous husband seems to feel the weakness of his case on general principles, for he seeks to justify his course by citing one of the letters he had opened, the letter in question being one that was not a request for a prescription. It is to be inferred that it was something quite different. But even that does not silence the lady. "Yes," she says, "I have a melancholic patient, one who is disgusted with life and asks me to restore its attractiveness for him. He would love; he is searching after love, and is in despair that he does not meet with it. As his languishing state is connected with hereditary tendencies, and as I think the best way of bringing him back to a wholesome mode of life lies in avoiding abruptness, I do not talk medicine to him in our interviews, and in his letters he answers me with sentiment. Must physicians be accused of leading their patients on to love them, because they humor their illusions before giving them drugs? Any woman may be faithless, as any man may be victorious; but if I were an actress, an artist, or simply a woman of independent means, unemployed, passing my days alone, I should be quite as much exposed, if not more, as in leading a life that shows me humanity in its miseries and in its injuries. You would have less correspondence to look over, but you would have more equivocal interviews to break up. Is it because I have

made myself estimable, by working, by acquiring knowledge, by trying to do good, that I am exposed to the injury of your suspicions? At bottom, it is not of my frailty that you are jealous, but of my dignity and my importance. If I were a frivolous nonentity I should possess your confidence; being a useful and serious woman, but less easy to deceive, I awaken your distrust. You are afraid of becoming my inferior, and you are trying tyranny to preserve the balance!"

The connubial tie having been strained to the degree exemplified in this state of antagonism, it may make little difference to the parties to the suit how the court decides, but the decision can scarcely fail to come up in the minds of female practitioners of medicine meditating matrimony, or in those of husbands called upon to consent to their wives' studying medicine.

The Early Diagnosis of Vertebral Caries.

Dr. George W. Ryan, of Cincinnati, read a paper on this subject before the Cincinnati Academy of Medicine, November 8, 1886, in which he expressed himself as surprised that so many excellent observers should regard the knuckle as the first symptom of vertebral caries. Over-estimation of the importance of a diagnosis before the kyphos is apparent, is impossible. If we believe that we have a constitutional disease, an essentially tuberculous one, beginning generally as a central ostitis of the body of the vertebra, the rational symptoms will be accordingly clear to us. It is now generally understood that this disease can be diagnosed in the incipient stage, and ought to be when the opportunity is presented. There are, however, cases which cannot be made out until the knuckle is visible. The first step is an accurate family history, directed especially to tuberculosis. The next, as to whether the child has passed through the infantile diseases or not, and as to convalescence. A tardy convalescence is often the starting point of this disease. You will have heard before you ask it of a trauma, real or suspected. Further questioning will give you the history of restless nights, moaning and disturbed sleep, a tired feeling, or a continued desire for support. The child very likely complains of an epigastric pain, if it falls it screams from pain, it walks with care, or if young does not walk at all. That it holds its back very rigidly, or the shoulders thrown back to an abnormal degree, or one shoulder appears higher than the other, that it does not stoop, or if it does it is with great care. Pain in the back is occasionally complained of, and this generally when a jar is sustained. The gait is characteristic, almost pathognomonic. There is a carefulness, a rigidity about the spine which is never found unless there is spinal disease. The physiognomy will give you a pinched and anxious expression. The child can only stoop with the spine held rigid, or from pain gives it up. Physical examination with all the clothing removed, may not give a trace of the angular curvature. Pressure to ascertain the existence of a soft spot is valueless. The examination as to mobility can be readily and painlessly made by having the child lie on its face and slowly bend the limbs with the opposite hand on the opposite side to the disease. It can thus be determined whether the column yields throughout, or whether there is any point where rigidity is present. If, with all this, rigidity is found, the diagnosis is unmistakable.

In the cervical region the symptoms are altogether different. Torticollis is often present, with an occasional occipital or post-auricular neuralgia or hyperæsthesia. Brushing the hair causes pain; there is considerable interference with the act of motion, and the deformity is often slight.

The acuteness of perityphlitis and perinephritis would, as a rule, enable us to exclude spinal disease. The flexible spine would also assist. The pressure test, though of some pathological and clinical value, should, on account of its cruelty, be entirely discarded. He had never seen tenderness from pressure over a diseased spine in the incipient stages in but two cases, and in one of these it was probably neuralgic. It is indicative of a periosteal rather than a central lesion. To diagnose the kyphosis of rickets from caries, take into consideration the general rickety appearance of the child.

He urged, in closing, the necessity of a physical examination, a clear history of the case, to keep in mind the pathology of the disease; and a diagnosis can readily be made, in the majority of cases, before the kyphosis appears.

The Transmission of Nervous Phenomena.

Two curious communications have been made at the Society of Physiological Psychology, and at the Biological Society, by Dr. J. Babinski, *chef de clinique* at the Salpêtrière, on the transmission of certain nervous phenomena from one subject to another by means of the magnet. Dr. Babinski states that all possible precautions were taken to exclude simulation and suggestion. In

the first series of experiments practiced upon hypnotizable hystero-epileptics, hemianæsthesia was transferred from one patient to another; and other symptoms induced in the first case by suggestion—such as flaccid or spasmodic paralysis, crural and brachial monoplegia, hemiplegia, paraplegia, coxalgia, and mutism—were disposed of in the same way. The results of these experiments show that the two subjects have the same relationship to one another as regards *transfert* as the halves of one body. In a second series of cases spontaneous hysterical paralyses were passed on to the hypnotized subject, the condition of the original patient being, as a rule, improved. The following observations lead M. Babinski to hope that these practices may be used as a mode of treatment. A young girl with spontaneous mutism was placed *en rapport* with a hypnotizable subject, who forthwith became speechless. No improvement was noted at the first *séance*, but after twelve experiments the speechlessness was replaced by extinction of the voice. The induced mutism was removed on each occasion by suggestion. A patient of the hospital remained hemiplegic and contractured after an hysterical attack. Placed *en rapport* with one of the subjects, the hemiplegia diminished, and disappeared after four sittings. In different cases of organic disease similar phenomena were observed. The person hypnotized was placed in the somnambulic phase of artificial sleep, with her back (as in the other case) to the patient. An infantile cerebral hemiatrophy, characterized by spasmodic hemiplegia and athetosis, was then dealt with, the effect being a sharing of the symptoms between the two, the patient keeping her athetosis and handing over her spasmodic hemiplegia to her companion. Another woman, with right hemiplegia and aphasia due to softening, retained her own troubles, but transferred a numbness to the subject which ended in hemiplegia. In a third case of disseminated sclerosis with paresis of the four limbs, trembling, and the pathognomonic pronunciation, the scapegoat developed all the symptoms, but in an exaggerated degree. I shall not stop to examine M. Babinski's views on the subject, but will contrast with these experiments those of one of the most experienced workers in this field at the same hospital. M. Jules Voisin has tried on two of his patients the action of medicine *à distance*, and also of metals and magnets. A number of dark bottles containing different drugs were sealed and numbered, the contents not being otherwise known. The subjects being placed in lethargy, somnambulism, or catalepsy, no medicinal effect could be induced. But when awake the production of the bottles was followed by hypnotism, with signs of nausea and vomiting. In this condition the mere mention of the name of any known drug was sufficient to give rise to a representation of its effects, manifestly due to suggestion and auto-suggestion. In the same manner, the subject being placed in one of the three higher phases of induced sleep, her state was in no way modified by the magnet. When awake, however, it produced an attack *if seen*.

The Prognosis of Croup.

Dr. F. Forchheimer, Professor of Physiology in the Medical College of Ohio, Physician to the Good Samaritan and Children's Hospitals, Cincinnati, in a recent paper before the Cincinnati Academy of Medicine, discussed in an interesting manner the above caption. Nothing, he thought, was so satisfactory and, perhaps, so profitable to the physician in his daily rounds, as an accurate prophecy concerning the course of a disease. In other words, to tell whether our case will be one of the 7.26 per cent. of cases of croup which recover or not. He did not think that medicinal treatment had very much effect on the diphtheritic membrane after it has extended into the larynx, but usually does more harm than good, especially the administration, with lavish hand, of emetics and caustics.

The next point in treatment which affects prognosis is, shall tracheotomy be performed? Out of 12,736 cases of diphtheritic croup collected by Monti which had been tracheotomized, 26.7 per cent. recovered. Admitting that some of these cases were fibrinous croup, yet the disparity is too great. For a good prognosis, the operation should be performed in every case, provided the physician has assured himself that laryngeal stenosis is present and has become dangerous to the patient. Seven of the author's cases were not tracheotomized, and but one recovered. The remaining twenty-five cases were operated upon and six recovered.

He has found the operation of intubation to fulfill all the indications of tracheotomy as far as the laryngeal stenosis is concerned. As yet it is too early to decide whether intubation will supplant tracheotomy or not. Cæteris paribus, the patient stands a much better chance with intubation than tracheotomy; there is no anæsthetic, no hemorrhage, no after-effects from septic infection

or pneumonia. One or the other or both operations are to be performed in all cases, irrespective of age, sex, or condition of the patient. In the cases in which the author had resorted to intubation, five in number, the stenosis was as effectually relieved as by tracheotomy. The lumen of the tube he thought sufficiently large to admit air readily. In one of his cases the tube had been swallowed, from faulty method of securing it.

General considerations have a very important bearing on the prognosis. Age, power of resistance, temperature, intensity, and extensiveness of the affection, must be carefully weighed. There are epidemics in which the mortality is simply frightful, do what we may. The further the child has gone into the stage of asphyxia, the less are the chances for his recovery. Much depends upon auscultation of the lungs. The presence of albumen in large quantities as much as five per cent. makes the prognosis very grave, especially if there are blood-clots found. If at any time after the operation the cough becomes dry or the expectoration ceases, we must fear the worst. A sudden rise of temperature—103° to 104° F.—is a serious symptom, and usually means a new deposit of membrane; increased frequency of respiration is always suspicious. There are very many complications which may cause death after the removal of the canula. These are local and remote. The former may be divided into diphtheritis of the wound, hemorrhages, abscesses, The latter, general septic troubles, followed by one of the most intense forms of anæmia, myocarditis, endocarditis, paralyses, trouble with the kidneys, and finally with the lymphatics. Prognostication is a very difficult task, yet made easier and in some cases exact by taking into consideration all the factors discussed above.

Resection of the Entire Shaft of the Tibia for Necrosis, with Reproduction of the Bone; Recovery.

Dr. W. C. Wile, of Newton, Connecticut, thus writes in the *Brit. Med. Jour.*, Oct. 9:

On May 8, 1883, I was consulted by the parents of Willie W., in relation to a running sore on the shin of his left leg. On external examination, I found three openings leading through sinuses, which were found to lead to dead bone. The tibia was much enlarged, and the boy showed a decided limp in his gait. He suffered considerable pain, especially at night, which had been controlled chiefly by anodynes. The boy was 12 years old, with hereditary scrofulous tendencies, and had the history of a fall, striking his shin violently against the iron rail of a railroad-crossing, causing, at the time, quite a severe contusion, which was followed by considerable inflammation. Soon afterwards, the bone commenced to enlarge, and had continued to increase in size up to the date of my first visit. The sinuses had opened about a year before, and continued to discharge ever since. The boy's general health was poor, he giving every evidence of the exhausting character of the discharges; and it was quite evident that the injuries he had received three years previously had lit up an inflammation of the periosteum, which had led to grave destruction of bone-tissue. It was also quite evident that, if the impairment of the general health was allowed to go on, the result could not be other than death; and the struggle, apparently, could not be a long one. I advised operative interference—of exactly what character, however, it would be hard for me to say until after an exploratory incision had been made. The family consenting, I put the boy upon a month's preparatory treatment, getting the secretions in perfect order, building up the general health with cod-liver oil, iron tonics, and liberal diet—beef peptonoids, and Murdock's liquid food—on which I largely depended to build up the patient.

On May 11th, with the assistance of Dr. J. J. Barry, of South Norwalk, who kindly administered the ether, and Dr. S. T. De La Mater, of Bridgeport, I made an incision along the line of the tibia down to the bone, cutting through the diseased periosteum, and carefully lifting it away. I found the bone to be badly diseased; so much so that, after consultation with the two physicians, it was decided to remove the entire shaft. In its removal, I was particularly careful not to injure the periosteum, peeling it up cautiously, and, as nearly as possible, keeping it intact. After removing the shaft, a considerable quantity of diseased bone, at each end, was removed with the gouge. After this was all removed, I packed the cavity with absorbent cotton moistened with a solution of carbolic acid (one to twenty). The boy rallied nicely from the operation; and, under the influence of the same treatment that was pursued in the preparation of the case, healthy granulations sprang up, and there was soon evidence of the production of new bone. After two months, the shaft was strong enough to allow the fitting of the shoe, to which were attached braces at the side, with the joints at the ankle, the upper ends of which grasped the limb just below the knee by a steel padded band. By this

time the external wound had healed, and the boy was put upon crutches. From this time out, the progress was uninterrupted. The tibia is now strong and well formed, and the termination of the case is all that could be desired.

Carbolic Acid Pulverisations in Erysipelas.

The employment of carbolic acid in the treatment of erysipelas has been recommended for some time. At a recent meeting of the Société Médico-Pratique (of Paris), Dr. Ory communicated the two following cases, which serve to demonstrate the efficacy of carbolic acid pulverizations, which was the only treatment used. The first case was that of an infant of three months old, suffering from erysipelas following vaccination. A fortnight had elapsed since vaccination, when Dr. Ory was summoned. The little patient was feverish, depressed and convulsed. The right arm was swollen, with a red patch about the size of the palm of the hand, in the centre of which was a vaccine pustule, covered by a scab in process of desiccation. Collodion, mixed with castor-oil, was applied to and around the red patch, in order to check the spread of the erysipelas, and an anti-spasmodic treatment was followed during the night. Finding the collodion applications ineffective in preventing the spreading of the redness, Dr. Ory had recourse to the treatment indicated by Professor Verneuil. The child was wrapped in cotton wool. Carbolic acid pulverizations were then used every hour for five minutes; a two per cent. solution was used; considerable improvement occurred. The convulsive movements ceased, diarrhœa disappeared, and the temperature fell from 40° to 38°. On the following day only those parts where the collodion still remained were red; it was removed, and by the evening, all traces of erysipelas had vanished. Rapid recovery, without any relapse, ensued. The number of pulverizations was gradually reduced (four in twenty-four hours on the fourth day), and all treatment was discontinued on the fifth. The second case was that of an old man, aged 69. The patient was ataxic and subject to obstinate constipation. The perinæum and gluteal regions were attacked by erysipelas. The carbolic acid pulverizations, applied in the manner above mentioned, had a satisfactory result. From the first evening the pain diminished after each pulverization, and on the third the tissues had almost recovered their normal coloring, and there was less fever. Dr. Ory concluded by stating his opinion that carbolic acid pulverizations might be used to the exclusion of all other internal treatment for combating erysipelas.

The Blood at Birth.

Dr. F. Kruger, of Dorpat, has been investigating (*Virchow's Archiv.*, 106, Hft. 1,) the condition of the blood of the fœtus at birth, and comparing its properties and composition with the maternal blood. The subject has been studied before. In some respects the present research confirms the previous ones—notably those of Becquerel and Rodier. Like those authors, Kruger finds a very slight comparative increase in the total solid constituents of the blood at this early period of existence; but he shows that in fibrin fœtal blood is markedly deficient—viz., about one-third of that contained in maternal blood. The amount of hæmoglobin is about the same as that of maternal blood, but it increases in quantity in the infant for some time after birth. Unlike the adult, there is no notable difference in the composition of blood in the two sexes. Fœtal blood at the moment of birth has a great tendency to coagulate, but coagulates slowly—*i. e.*, the process begins early, but continues for a long time before it is completed. Inquiring into the reason of this, he directed attention to the factors which, according to Schmidt, are essential to coagulation—viz., the leucocytes and blood-plasma. Three possibilities presented themselves: either there is a diminished activity of the blood-plasma in causing the liberation of "ferment" from the corpuscles, or the number of leucocytes must be less than in the adult, or these corpuscles part with the ferment less readily. On the first hypothesis, coagulation ought not to be quickened on the addition to the plasma of more lymph corpuscles; but the contrary is the case. Nor is there any dimunution in leucocytes, the absolute and relative number per cubic millimetre being the same as in the adult. It is concluded, therefore, that the reason of the slowness of coagulation of fœtal blood depends on the nature of the white corpuscles, and their slighter readiness to break up.

A Case of Poisoning by Iodide of Potassium.

In a recent number of the *Berliner Klin. Wochenschrift* is an account of a case recorded by Dr. Wolf, of Goritz, of poisoning by the medicinal administration of iodide of potassium, which is interesting as being a most

remarkable instance of that individual peculiarity which we call idiosyncrasy. In this particular case the amount of the drug taken was no more than four tablespoonfuls of a three per cent. solution in about thirty-six hours, and the purity of the drug was shown by chemical analysis; but so great was the susceptibility of the individual that after about eight days a fatal issue set in, which there is every reason to attribute to the use of the medicament. The patient was suffering at the time from subacute kidney disease of about three months' standing and cardiac hypertrophy, which facts we must bear in mind in estimating the idiosyncrasy. After the administration of four tablespoonfuls of the above-named solution, the face became swollen and covered with pustules, papules, and bullæ, and twenty-four hours after the mucous membrane of the mouth, pharynx, and alimentary canal became attacked in a similar manner. On the cessation of the drug, no amelioration ensued, and in eight days the patient sank into a state of collapse and died. No necropsy was made. This is the second case of the kind recorded, Morrow having published one in which the administration of the drug to a person suffering from renal and cardiac disease caused a pemphiginiform eruption, with similar symptoms and result.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——A convenient little work, intended for use in schools, is the "Principles and Practice of Hygiene for the School and the Home," by Dr. Ezra M. Hunt, President of the American Public Health Association. It is well written and neatly printed (pp. 96, published by Ivison, Blakeman, Taylor & Co., New York city).

——Dr. H. McHatton, of Macon, Ga., has added another to his valuable studies on malarial disease in a reprint entitled "Malarial Hæmoglobinuria."

——The treatment of diphtheria is discussed in an essay by Dr. J. Pirnat, of Evansville, Indiana. He urges the use of a diphtheritic powder whose formula he gives.

——In a reprint before us, Dr. Samuel Theobald, of Baltimore, discusses the question whether the amblyopia of squinting eyes is a cause or a consequence of the squint, and leans to the opinion that the squint is the cause of the amblyopia.

——The last number of the Physicians' Leisure Library is "Antiseptic Midwifery," by H. J. Garrigues, M. D. It is a well-written monograph. (Pp. 128; price 25 cents; published by Geo. S. Davis, Detroit.)

——An interesting study of the human color sense has appeared as the joint production of Dr. L. Webster Fox and Dr. George M. Gould, of this city.

——Dr. Thomas A. Ashby, of Baltimore, has reprinted his suggestive article in regard to the method of operating during the same anæsthetization for laceration of the cervix uteri and ruptured perineum.

——A discussion of the curette as a diagnostic and therapeutic agent in gynecology and obstetrics has appeared, by Dr. B. B. Browne, of Baltimore.

——"The Surgery of the Pancreas, as Based upon Experiments and Clinical Researches," is the title of an able essay by Dr. N. Senn, of Milwaukee, reprinted from the *Transactions* of the American Surgical Association.

——Dr. Mary A. D. Jones, of Brooklyn, details in a reprint recently received the removal of the uterine appendages in nine consecutive cases.

——Dr. Burt G. Wilder, of Cornell University, continues his fruitful studies on the brain, and we are indebted to him for reprints of several brief articles on the subject.

—The presidential address of Dr. Charles K. Mills before the American Neurological Association has been printed in pamphlet form. Its title is "Arrested and Aberrant Development of Fissures and Gyros in the Brains of Paranoiacs, Criminals, Idiots, and Negroes."

——Dr. Wesley M. Carpenter, of New York city, has published his obituary addresses on Drs. Austin Flint and Marion Sims.

——An article on contagious eye diseases, by Dr. Joseph A. Andrews, of New York city, has been reprinted.

——In a reprint before us, Dr. D. W. Cathell describes a case of pregnancy complicated with uterine fibroids and measles.

—Lady Wilson, the widow of Sir Erasmus Wilson, died recently. The Royal College of Surgeons now becomes entitled to the legacy of $1,000,000 left by Sir Erasmus.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year, $5.00
Quarterly Compendium of Med. Science, - 2.50
Reporter and Compendium, - - - 6.00
Physician's Daily Pocket Record, - - 1.50
Reporter and Pocket Record, - - - 6.25
Reporter, Compendium and Pocket Record, 7.00

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M. D.,
115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE RUSH MONUMENT FUND.

It is by this time very generally known that a movement is on foot (and successfully so) for the purpose of erecting a monument at the national capitol (Washington) to the memory of Dr. Benjamin Rush of Pennsylvania. Any man, with a grain of sense, can easily understand that our profession, as a whole, are an *awfully* selfish, and we may say an awfully *mean* set of men, but we trust that our opinion will be proven erroneous on this occasion.

Congress is placing in the Memorial Hall of the Capitol the statues of the founders and men of mark of the Republic, each State contributing those of two of its most eminent *citizens*, and the collection already includes the Winthrops, Samuel Adams, Hamilton, Livingston, Clinton, Roger Williams, Nathaniel Greene, Collamer, Fulton, Roger Sherman, Trumbull, Baker, William King, Muhlenberg, and Ethan Allen.

Of the Presidents, Washington, Jefferson, Jackson, Lincoln, and Garfield have already, and Grant and Taylor are soon to have, their effigies in stone or bronze. The military and naval heroes of the country have been honored in the persons of Scott, Thomas, McPherson, Rawlins, Green, Farragut, and Du Pont, and to these McClellan, Hancock, Shields, McDonough, and Barry are about to be added. A resolution is pending to erect a statue to Stanton as Secretary of War. The law has its representative in Chief-Justice Marshall, and science is recognized in Professor Henry. The Church is to have its statue to Wesley; the deaf mutes have taken action toward a memorial of their eminent teacher, Gallaudet; and philanthropy is to have a monument to Peabody.

Other monumental adornments of the national capital are the Emancipation Statue in Lincoln Park; the Naval Peace Monument at the foot of the Capitol; the statues of the world's great artists, among them the American Crawford, surrounding the Corcoran Art Gallery; and the statue of Martin Luther overlooking Thomas Circle. Congress is further providing for heroic statues of Columbus, Penn, Lafayette, and Anthony Wayne; and the Italians are contributing for one to Garibaldi.

In concluding his address to the profession, Dr. Gihon, with his usual sanguinity, says: "It may be approximately estimated that $40,000 will be sufficient to erect a monument that will be fitting and unexceptionable as a work of art, and it does not admit of question that this sum can be speedily raised

among the 106,000 physicians and students of medicine in the United States."

We think that it does admit of question, though it *ought* not so to do. We have 80,200 physicians (not 106,000) in this country; each man could give fifty cents (many could give much more), and we emphatically say that any man who does not at least give fifty cents to this most worthy object ought to be ashamed of himself.

ONE CAUSE OF HÆMOGLOBINURIA.

An anæmic syphilitic woman, æt. 26, always suffered after colds, psychical emotions, and once also after a prolonged walk, from hæmoglobinuria, accompanied by decided increase of temperature. The bleeding, however, lasted but a short time. All treatment was in vain; only decided doses of quinine had in so far some effect, as the hæmoglobinuria remained away for a longer period. Leube, who reports the case (*Munich Med. Wochensch.*, 14, '86,) is of the opinion that individuals laboring under the complaint in question have a special tendency toward the separation of the struma from the coloring material of the blood. As soon as in consequence of any of the causes enumerated the stroma separates from the hæmoglobin, hæmoglobinuria is of the most consequence. The broken-up corpuscles are carried into the spleen (Tonfik) and then produce the splenic tumor, also present in the above case. The hæmoglobin, however, is changed in the liver to bilirubin, but that organ can thus change but a certain portion of it, the balance is carried off by the kidneys, and gives there rise to bloody urine. Is the quantity still larger, so that the kidneys can neither secrete all, icterus is the consequence, the liver changing the superfluous quantity to bile-coloring matter. In Leube's patients this was also observed, for during the attacks the liver was enlarged in size, and the stools had a much deeper color than normally.

PSORIASIS VULGARIS.

From a large number of cases of psoriasis vulgaris under his charge, Dr. Frederick Hanmer (*Deutsch. Med. Zeit.*, September 20, 1886,) drew the following conclusions: In one-half of the male patients the knee was found completely free from the disease; in the females almost never; in one case palmæ and plantæ were covered with it.

Very frequently hereditary influences are noticed; once father and daughter suffering from the same psoriasis, were in the hospital at the same time, and in the same family the wife and sister at home also had the disease. Of microbes only the normal skin microphytes, described by Bizzozero, were met with, and trials of inoculation with them or with psoriasis scales and particles of diseased skin were utterly without any result.

The treatment most successful was the local application of chrysarobin in chloroform (1 to 10); the parts of the skin brushed over with it had later also some traumatisin applied.

NOTES AND COMMENTS.

Antagonism between Atropine and Morphine.

At a recent meeting in Berlin, Herr Lenharz, of Leipzig, read a paper (*Prager. Med. Wochenschr.*, No. 42), on the alleged antagonism between atropine and morphine, considered both clinically and experimentally. He had come to the conclusion that no such antagonism existed, for the following reasons:

First, the antidotal doses of atropine have far too wide a range. As a rule, enormous doses are given, often without success, while, at the same time, recoveries from morphine-poisoning are recorded after merely nominal doses of atropine (.015 gramme, and even less than this); secondly, the uncertainty of the indications. Johnston (of Shanghai) would resort to atropine in all cases, in spite of a weak irregular pulse, whilst Wood makes the condition of the respiration the criterion, and Binz discards the use of atropine if the pulse be rapid and small; finally, atropine does direct harm. Binz had recommended atropine on experimental grounds, bnt Binz's experiments had not been sufficiently complete, that is, only enough morphine had been given to make the animals sleep, but not enough to give them convulsions. Animals killed by large doses of morphine did not die from lowered pressure, nor from embarrassed breathing, but from the exhausting convulsions. Of 132 cases of morphine-poisoning collected by the author, 59 were treated with atropine, with a mortality of 28 per cent.; of the other 93 only 15 per cent died. In eight experiments with morphine on animals, atropine made no difference—the animals died just as soon as without it.

Microbes in the Bile-Duct.

Before the Anatomical Society of Paris,

Dr. Netter read a paper on the presence, normally, of micro-organisms during life in the last part of the bile-duct. By tying this duct, these organisms passed into the liver, and eventually into the blood. They were of two different species: the staphylococcus aureus, readily recognized by its orange-yellow color, and a bacillus growing in opaque white colonies; injected into the liver or gall-bladder, the bacillus is alleged to produce a peculiar degeneration of the hepatic cells; it is also affirmed to be capable of inducing a vegetable endocarditis. In infection by the staphylococcus, the rectal temperature was markedly elevated. The mucous lining of the gall-bladder and large ducts became ulcerated, whilst abscesses were found in the liver itself and other organs of the body. After infection by the other microbe, the temperature was notably lowered, and the liver afterwards presented marked evidence of cell-change. Brieger has cultivated the staphylococcus from a case of purulent infection after calculus obliterating the bile-duct. In a case of grave icterus associated with a generalized acute miliary tuberculosis, the cultivations from the blood and the spleen showed the existence of the staphylococcus aureus. In a case of icterus secondary to alcoholic cirrhosis during the early stage, when the liver was enlarged, both organisms (staphylococcus and bacillus) were found in the blood. In primary icterus, too, it was stated that the staphylococcus had been detected, by cultivation, in the blood.

Coutusion over the Sacrum; Suspected Injury to the Vesiculæ Seminales.

G. H. came under the care of Dr. Harrison Younge (*Brit. Med. Jour.*) August 28, 1886. The previous day, while out riding, he had been thrown from his horse on to some hard ground. When he saw him, he found a severe contusion over the sacrum. There was great swelling and ecchymosis, but no signs of any deeper injury. Under rest and warm fomentations these disappeared in about a week; but, for some time afterwards, soreness and stiffness of the adductor muscles of both thighs remained. About ten days after the accident, he began to suffer from priapism, with nocturnal emissions. On the first occasion on which the latter occurred, he was greatly alarmed to find, on getting up in the morning, that his night-clothes were deeply stained with blood. On the second occasion he was able to examine the semen. It was of a deep reddish-brown color, and appeared to consist of small semi-isolated masses. These showed little tendency to coalesce. Under the microscope, the color was seen to be due to broken-down blood corpuscles. The emissions continued for about a fortnight, till the semen gradually became normal in color and appearance; then they ceased. There can be little doubt that these symptoms were due to contusion of and perhaps to rupture of a small blood-vessel within the vesiculæ seminales. The doctor believes they were quite independent of any injury to the spinal cord. The only treatment adopted was rest.

Caffeine in Heart Disease.

Dr. Otto Seifert (Wurzburg) undertook, in the course of last year, a series of researches on citrate of caffeine. All the patients to whom he administered it were suffering from organic affections of the heart with imperfect compensation. In one case there was chronic nephritis, with generalized œdema. The caffeine was given in seven cases, sometimes in repeated doses, at others all in one dose. According to Lepine, the daily quantity should be from one to two grammes. The principal advantage which has been claimed for it is that it quickly improves the action of the heart and regulates the cardiac beats. It is also a diuretic, and has no cumulative action. One to two grammes of caffeine should be given in twenty-four hours. Opinions as to the value of the drug are conflicting; the principal drawback to its use seems to be that, owing to its speedy elimination, its action only lasts for a short time. In those cases where compensation has been re-established, the action of caffeine may be as prolonged as that of digitalis. The general condition is influenced in a striking manner; the palpitations, the dyspnœa, and, as a rule, the insomnia, also rapidly disappear.

A Case of Tubercular Inoculation in an Infant.

Syphilis has frequently been conveyed by the process of sucking the wound in ritual circumcision, but the communication of tuberculosis in the same manner has been met with more rarely, and is less known. There are on record two cases observed by Lindmann and twelve by Lehrmann, but without examination for bacilli. Elsenberg, a Polish doctor, relates the following:

A priest suffering from tubercle of the lungs and of the larynx, with bacilli in his sputum, had circumcised an infant. When

seen, at the age of five months, the wound in the penis had become transformed into an ulcer, covered with a yellow and adherent deposit. There was a hard nodule in the prepuce near the foreskin. On both sides the inguinal glands were much swollen, and from an opening in the left side there escaped an opaque serous fluid, containing caseous particles. In the mastoid region in the right side was a large fluctuating abscess. The other lymphatic glands were unaltered. The child died of erysipelas and tetanus, after the removal of the caseating glands and the opening of the mastoid abscess. Numerous tubercle bacilli were found in the ulcerated prepuce and caseous lymphatic glands.

Polymorphism of the Comma-Bacillus.

At the Congress at Strasbourg, Herr von Sehlen (Hanover) spoke at length on the polymorphism of the comma-bacillus of Koch. Koch had already asserted that the cholera-bacillus might, in the course of its evolution, pass through different forms—the comma form, that of the letter S, the spiral, and certain coiled filamentous forms. Cultivations made with cholera dejecta, obtained at Naples, contained, besides the comma-bacillus, a large number of small, very short rectilinear rods, as well as spherical corpuscles, resembling micrococci. At first it was supposed that bacteria foreign to cholera were accidentally present in the cultivations, but these rods and micrococci cultivated on gelatine produced pure comma-bacilli, presenting the same characteristics as those observed in the cultivations of the adult comma-bacillus. Herr von Sehlen agrees with most other competent students that the morphology of bacteria is not sufficient to determine the species.

Hydrophobia.

In the *Brit. Med. Jour.* (Nov. 13), Dr. Sidney Roberts related a case of this disease occurring in a boy aged five, under his care at the Public Hospital. The child was bitten on the thumb, which was at the time (half an hour after the bite) cauterized with nitrate of silver. Symptoms began on the forty-second day after the bite, with restlessness and pain in the bitten part. On the forty-fifth day he refused food and drink. He died on the forty-eighth day after the bite. Salivation was conspicuous by its absence throughout the disease. There were no lyssi. Various remedies were administered, but chloroform-inhalation was the only remedy that afforded temporary relief. An interesting point was, that two other children were bitten by the same dog—one an hour, and the other only five minutes, previously. Both were sent to Pasteur fifty days after the bite, and are now, eighty-three days after the bite, in robust health.

Multiple Papilloma of the Larynx.

Before the Manchester Pathological Society recently, Dr. Hodgkinson showed several small papillomatous growths from the larynx, coughed up at short intervals by a woman, aged forty. When first seen, fourteen months ago, she was suffering from complete dyspnœa and aphonia. Laryngoscopic examination revealed the presence of three growths. Marked improvement resulted from repeated applications of the galvanocautery, and the patient ceased to attend. After an absence of four months she was admitted into the Throat Hospital at Bowden with such urgent symptoms that tracheotomy was performed by Mr. Hardie. Dr. Hodgkinson called attention to a point of great interest, namely, the steady diminution in the size of the growths under the influence of the physiological rest since the operation. Microscopically, the growths were of a simple character.

The Myopathic Face.

At a recent meeting of the Société Médicale des Hôpitaux, M. Landouzy exhibited three cases of progressive muscular atrophy affecting the face, shoulder, and arm. There is a family likeness in the different cases, owing to the existence in all three of the "myopathic face." This peculiarity of the countenance is best seen when an attempt is made to get signs of animation in the face. It is found that the patients cannot whistle, blow, extinguish a candle, make grimaces, or kiss, owing to the atrophy of the orbicular muscle of the mouth. A good description and phototype illustrations of this affection may be seen in Dr. Gowers' manual. This form of myopathy appears to be less rare than has generally been supposed, for Landouzy has himself met nine cases in the course of five years.

Hepatic Bronchial Fistula.

Before the Medical Society of London, November 8, Dr. de Havilland Hall related the case of a patient who, in 1876, complained of anginal symptoms. He came under observation again in 1881, having in the meantime enjoyed good health, but hav-

ing lately suffered from pain in the region of the liver, followed by jaundice. Other attacks followed, with increase in the jaundice. Ultimately, he vomited bright bile, and large quantities of bile-stained fluid, subsequently ascertained to come from the lungs. The patient made a good recovery, so that the anatomical lesion remained obscure. Dr. Hall reviewed the literature on the subject, in which the fistula was attributed most often to hepatic abscess and hydatids.

Lister's Latest Antiseptic Dressing.

Lister's latest antiseptic dressing is known as salalembroth. He uses it exclusively in his wards, with fine results. It is a double mercurial salt, made by the sublimation of a mixture of perchloride of mercury and chloride of ammonium. It is very soluble, and has not been used in medicine since the time of the alchemists. All dressings—gauze, cotton, wool, bandages, lint, bedding, patient's underclothing, etc.—are soaked in a 1 to 100 solution, and dried. He colors these dressings with aniline blue, 1 to 10,000, so that when an alkaline discharge comes in contact with the dressings, the blue is removed and turns reddish, enabling him to see where the discharge has been and its quantity, however small or large, moist or dried.

Methylal.

Methylal is believed by Signor Personali to possess anæsthetic and hypnotic properties. It is a mobile colorless liquid. Suspension of reflex action with deep unconsciousness, preceded by anæsthesia, were observed after subcutaneous injections in dogs. The effects in rabbits were less marked; the heart-beats were somewhat increased in number, the blood-pressure slightly lowered, and the respiration was slowed and rendered more profound. It is believed also to antagonize the spasmodic action of strychnia. It relieves abdominal pain in human beings, and as an ointment or liniment causes anæsthetic effects on the skin. As a liniment, the proportion is 5 per cent. of methylal in 85 per cent. of oil of almonds; as a syrup for internal administration, 1½ in 100 parts of simple syrup.

Enlargement of a Limb from Lymphatic Obstruction.

Before the New York Surgical Society Dr. Weir showed a photograph of a young girl whose right thigh, and afterward the leg, had become enlarged so that the difference in the circumference of the two limbs was six inches in the thigh and two inches and a half in the leg. The skin was now slightly irregular, and the upper part of the thigh was studded with little prominences which gave issue to lymph freely on being opened. Nothing abnormal was to be felt in the abdomen. He had first seen the patient in 1883, when she was twelve years old; the enlargement had then existed for a year. He ordered an elastic bandage, and it was used for over a year, but without benefit.

Iodoform Vaseline in Small-pox.

Dr. Colleville recommends in the *Union Médicale du Nord-Est* a vaseline ointment of iodoform, of the strength of 1 to 20, as not only an antiseptic emollient gratifying to the patient, but as somewhat anæsthetic, and as preventive of the formation of foul-smelling scabs and of pitting. Dr. Colleville has observed that in a case of confluent small-pox where iodoform ointment was frequently applied, the vesicles were prevented from developing into pustules. No signs of iodoform poisoning have been observed in any of the ten cases in which this treatment has been employed.

On a Means of Recognizing that the Umbilical Cord is Round the Neck of the Child.

Dr. F. R. Humphrys, in the *Brit. Med. Jour.*, says that in nearly all the cases of this occurrence he has come across, the mother has cried out, much the same as she would in the early part of the first stage of labor, and complained of sharp acute pain, which stands out in curious contrast with the bearing-down of the latter part of the second stage of labor (when the head is on the perineum), at which it is obscured. He has very rarely noticed this cry when the cord was not round the neck of the child.

Removal of a Tumor from the Cerebellum.

On October 30, Mr. Bennett May removed a tumor from the cerebellum of a child under the care of Dr. Suckling in the Queen's Hospital, Birmingham. The child had been in a condition of stupor for some weeks, and was growing rapidly worse. The tumor, as had been diagnosed during life, was situated in the right lobe of the cerebellum. The operation was performed on the lines laid down by Mr. Victor Horsley, but the child only survived three hours. The growth, we are informed, was tubercular.

Diabetes in Childhood.

An interesting case of diabetes in a child of four years old has been reported by Dr. A. Winckler (*Münch. Med. Woch.*). The rarity of the disease in a child, and its rapid development, rendered the case one of peculiar interest. There was an hereditary predisposition, as a member of the family had been affected with diabetes, but the great quantity of sugar which had been given to the child certainly hastened the development of the disease in this case. Cantani has stated that 90 cases out of 218 of diabetes are due to sweets and farinaceous food.

A Case of Lupous Stricture and Atresia of the Female Urethra.

Dr. Herman read notes of this case before the Obstetrical Society of London. The patient was forty-eight years of age. Retention of urine occurred, and the meatus was found to be blocked with fibrous out-growths; one labium minus was hypertrophied, the other perforated, but there was no visible ulceration. The channel was opened with a trocar, and kept patent by bougies. Only two cases appear to have been recorded.

The Obstetric Bandage.

Professor Czerny, of Heidelberg (*Centralblatt für Gynäkologie*, No. 3, 1886), attributes the pendulous abdomen of some women who have borne children to the want of proper bandaging after labor. Observation has shown that the shape of the abdomen and the tone of the abdominal muscles are decidedly improved by the use of the obstetric binder, not only during the first week, but also for several weeks after confinement.

Muscular Rheumatism Due to the Use of Tobacco.

I have met a great many cases of muscular rheumatism (says Dr. Edward Anderson in the *Maryland Medical Journal*) due to the use of tobacco in some form, mostly in the shape of snuff placed under the tongue. All remedies were unavailing whilst the use of the weed was indulged in. Every practitioner, I think, on meeting with a case of the above disorder, should inquire as to the tobacco habit, and correct it, if possible.

New Antipyretic.

It is asserted that the leaves of a Ceylon plant, the michelia niligerica, have been found to possess marked antipyretic properties, a decoction of the plant acting in this respect more powerfully than cinchona. A peculiarly bitter principle is also said to have been extracted from the leaves.

Correspondence.

A New Mode of Extracting the Placenta.

Eds. Med. and Surg. Reporter:

In all cases of child-birth where the placenta is not adherent but detached, and retained either in the uterus or vagina, and is not delivered by the ordinary pains necessary to the delivery of the secundines, I adopt the plan of changing the axis of the pelvis by requesting the patient to bow or bend her back by lifting her hips from the bed. In order to assist her in making this change in the axis of the pelvis, I usually place my hand under the small of her back or sacral region, and closing my hand, I let the small of the back rest upon my closed hand. When the brim of the pelvis is thus tilted forward, its axis is changed. Then as soon as a pain comes on I request the patient to bear down, while I make gentle traction upon the cord, and the retained placenta glides out with astonishing ease.

J. B. Johnson, M. D.

Washington, D. C.

News and Miscellany.

The Legal Aspect of Antisepsis.

Actions for malpraxis, although of comparatively rare occurrence, are still sufficiently common to make a want of care in diagnosis and treatment as undesirable from a pecuniary point of view as it is from a professional standpoint (says the *Brit. Med. Jour*). Such proceedings, when they are taken, generally rest on alleged gross and apparent want of skill or attention; but an article recently contributed to the *Vierteljahr f. Gerichtl. Med.*, by Dr. Carl Deneke, of Flensburg, again discusses the question whether it be not criminal neglect on the part of a surgeon to abandon the principles of the antiseptic method in the treatment of injuries or of operative wounds, unless the fulfilment of some vital indication renders adherence to these principles impossible. A surgeon who had carried out antiseptic precautions in their integrity, would not be held responsible, in a court of law, for any unfavorable course the wound might take, and in cases where complaints are lodged against

surgeons on account of alleged want of skill in the treatment of wounds, the legal authorities ought, in the course of their preliminary investigation, to submit the case to a medical faculty for its opinion. The value of the antiseptic method of surgical treatment is so widely recognized, though in its modern form it is of quite recent origin, that the administrators of the law are now forced to consider seriously whether the neglect of antiseptic precautions, in the treatment of injuries, is not to be regarded as criminal, if the injured person died apparently from such neglect. There is however a sufficient range of method and practice in the system called antiseptic to make it a somewhat difficult task to say what is and what is not antiseptic treatment. Many surgeons who openly repudiate the antiseptic method as commonly practiced, nevertheless contrive to obtain results up to the average; and this, no doubt, is due to the fact that the essential feature of antisepsis is perfect cleanliness. No one detail of the treatment can in itself be held to constitute antisepsis; we may drop the spray, as indeed the founder of the system has done; we may dispense with the use of carbolic acid, and still the treatment may be antiseptic, both in name and effect. The question would be, therefore, whether or not the surgeon carried out the operation in a proper and cleanly manner. But even with the most elaborate and pains-taking precautions for maintaining the aseptic condition, suppuration may, and in a certain number of cases does actually occur, without, on that account, any except a theoretical blame attaching to the operator. It is not easy to see, therefore, how a legal liability could ever be established unless particular details of procedure are raised to the dignity of a dogma, to modify or omit which would constitute liability. The discussion, therefore, is entirely unprofitable, for any attempt to found an infallible dogma on a method of practice is not only certain to break down, but has an injurious influence on the free development of scientific thought.

President Cleveland Showing Signs of the White House Wear and Tear.

A Washington despatch in the *Baltimore American* says:

"Naturally those at the White House do not care for it to be known outside that the President is so sick that he has to remain in bed. Therefore the bulletins from the sick-chamber are that he is about the same. But the President is not the same. He was not so well to-day (last Saturday), and all who called were informed that he was not able to see them. One of the Assistant Secretaries of the Treasury had some important business with him, but at ten o'clock was told that the President was unable to get up, and that his knees gave him so much pain that he could not think of work. The President does not care to call in a doctor, and hence he is still using the old remedies prescribed for him when he had an attack at Albany.

"Those who have watched the President say he could not stand the life he has been leading, shut up, as he has been, fourteen or fifteen hours every day, working at his top speed, taking no exercise or pleasure. They shook their heads and said something would come of it. Now it is rheumatism, and they say that he can thank his stars that it is nothing worse, and that he ought to take a warning."

Salt Fish as a Military Ration.

Salt cod-fish has been introduced among the articles of diet of the French soldier. The Minister of War, after having consulted the Sanitary Council of the army on the subject, has ordered salted fish to form part of the ordinary military rations. It must be of good quality, and captains commanding regimental companies and squadrons or batteries of artillery, with a view to avoid any possible accidents, are ordered to watch that no fish is used which presents traces of alteration, as is frequently indicated by a rose-tint of the muscular tissue, or which is deteriorated in any other respect. One of the chief purposes aimed at in the introduction of salted fish as a part of the rations of the French troops, is announced to be the help the consumption of it will afford to the crews of the fishing vessels, from which the most valuable recruits of the Military Marine, or Government Naval Service, are obtained. Salt cod may be acceptable to the troops as a variation in diet, but can hardly be regarded as an economical description of food, so far as its nutritive qualities are concerned.

She Was Not Spayed.

The *Medical Press and Circular*, September 8, 1886, vouches for the truthfulness of the following:

"A certain operator proposed to remove 'the uterine appendages' from a patient under his care, and he asked a gentleman present if he would like to examine the patient, saying she had been suffering for years with

an acute pain, that life was a burden, etc. The gentleman, struck by the full, round, rosy cheeks and red lips of the woman, first asked her how she slept at night. 'Oh, very well, thank you,' was the reply. 'You have no pain at night, then?' was the next question. 'Oh, no,' she answered. 'Have you pain all day long?' continued the questioner. 'Not all the day through,' she replied. 'Have you pain every day?' he went on. 'No, not every day,' was the answer. 'How often does the pain come on then?' the gentleman continued. 'Oh, three or four days a month,' was the innocent reply, much to the amazement of the questioner. The would-be operator was heard to mutter something about 'getting any answer you like,' but it will be satisfactory to learn that the patient saved her ovaries on that occasion, at least."

Proposed State Monopoly in Alcohol in Switzerland.

Undeterred by the failure which has attended Prince Bismarck's attempt to establish a spirit monopoly in Germany, the Swiss government are trying to pass a measure based on similar principles. The National Council has referred the projected bill to a committee, which, by eight votes to three, has declared itself in favor of the principle of the measure. A compromise has since been arrived at between the advocates and opponents of state monopoly in alcohol, which virtually concedes to the former all essential points. It is consequently not unlikely that a bill may shortly become law which hands over to the Federal government the importation, manufacture, and refining of spirits within the country. Vested interests such as those of the distillers and of the producers of potatoes for spirit manufacture will receive compensation.

A Medical Student's Suicide.

Thomas Elliott, a student at Jefferson Medical College from Beaver Falls, Pa., fatally shot himself last Saturday. When the other students in the building entered the room after hearing the pistol shot, Elliott was found lying on his bed not quite dead, but by the time a physician, who happened to be in the building, arrived, life was extinct. The young man was twenty-four years of age, not addicted to drink, with no bad habits, and religiously inclined.

Elliott was, however, of a very retiring disposition, could not be drawn out in conversation, and was swayed so far by his reticence as to dislike to eat at the table with the others. He was a hard student before entering the college. Worriment over his studies, coupled with his naturally melancholy disposition, led, no doubt, to the suicide.

Prizes Offered by the French Society of Hygiene.

The Société Francaise d'Hygiène proposes for competition the following subject for the year 1887: On Seditariness in Schools (primary and secondary), and on Intellectual Over-pressure in Superior Special Instruction. The first part will set forth the facts and observations which establish the evil; the second part will indicate the best means for combating it. The work should not exceed thirty-six pages of an 18mo. pamphlet. The prizes offered are a gold medal of the value of 500 fr. ($100), and two silver medals of the value of $30. The memoirs (written in French, English, German, Spanish, and Italian,) should be forwarded in the usual academical form to the Secretary of the Society, 30 Rue du Dragon, Paris, before April 1, 1887.

Influence of Light on Ferments.

It would seem to be necessary to keep away from the light all ferments that are meant to act in the darkness of the stomach and duodenum. Mr. Arthur Downes has made observations on the influence of light on various ferments now frequently prescribed in cases of digestive disorder. Active solutions of malt diastase, pancreatic diastase, and trypsin, were all rendered inactive by an exposure to sunlight in half-filled flasks for the space of one month. A solution of pepsine also became inactive after a similar amount of exposure. Even rennet has some of its properties enfeebled. Other flasks (control experiments) were kept in precisely the same conditions, with the exception that they were not exposed to light. The ferments in the vessels kept in the dark remained perfectly active.

Poisoning by Misadventure.

A woman at Budwith, England, has met her death by taking, in mistake for a dose of cough medicine, a tablespoonful of a liniment presumed to be aconite liniment. The deceased discovered her mistake at once and took a mustard emetic, which produced slight vomiting, but she died within an hour of taking the liniment. There was no time to procure medical aid, the nearest medical

man residing four miles away. The bottle containing the liniment was the usual "poison" bottle of blue-fluted glass, and quite unlike the other. The coroner did not call for medical evidence, and it is, we are informed, rather the exception than the rule for him to do so.

Official List of Changes

OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FOR THE TWO WEEKS ENDED NOVEMBER 27, 1886.

Williams, L. L., assistant surgeon. Granted leave of absence for twenty-four days, to take effect when relieved, November 15, 1886.

McIntosh, W. P., assistant surgeon. Granted leave of absence for twenty-seven days, November 26, 1886.

Norman, Seaton, assistant surgeon. When relieved, to rejoin station (New York); granted leave of absence for twenty-three days, November 27, 1886.

He Saw He Was from Chicago.

A well-known dentist contributes the following to the *Boston Record:*

A gentleman from the boundless West was calling at the "parlors" for consultation, and as the interview was about terminating, his eye chanced to fall upon the doctor's diploma, the leading line of which, in very black text, ran thus: "Academia Chirurgia, Dentium," etc., etc.

As the Chirurgia struck him, his face suddenly lighted up, and, extending his hand energetically, he exclaimed: "Why, doctor, I didn't know that you were from Chicago. Shake!"

"In the Arms of Morpheus."

Some boys at Sunderland (England) got a caution the other day likely to last them for some time. They stole from a chemist's a bottle of what they thought were cough lozenges; these they carried off as a great prize and distributed among their friends. The lozenges turned out to be morphia, and at least six of the boys fell into a profound sleep, and were awakened with some difficulty after a long time; they then felt what is termed "the after-damp" in mining districts, viz., sickness and headache.

Drs. Joseph Leidy and S. Weir Mitchell Honored.

An informal dinner was given at the Hotel Victoria, Sunday evening, November 9, the anniversary day of the founding of Harvard College, to the three gentlemen recommended by the medical faculty for the degree of LL. D. Drs. Leidy and S. Weir Mitchell, of Philadelphia; Dr. Billings, of Washington; President Gilman, of Johns Hopkins University; Prof. E. S. Morse, of Salem, were guests of fourteen gentlemen graduates of the College and the Medical School. The occasion was quite informal, without speeches, and proved very enjoyable.

A Song that Prevented a Riot.

The *Denver News* says that "Thomas Nast, the artist, visiting Denver, was talking the other night about the night of Mr. Lincoln's inauguration. He said that every one feared a riot. A man stepped out on a balcony of one of the big hotels, and began to sing "The Star-Spangled Banner." A crowd gathered, and soon the chorus was swelled by a thousand voices. The strain was relieved, and Washington was itself again. 'The Star-Spangled Banner' saved it."

The Relation between Physician and Patient.

A French court recently rendered a decision which is of considerable interest in connection with vital statistics. A physician refused, in a suit against a life insurance company, to testify as to the illness from which his patient died; and the court sustained him in his position, holding that the physician must be the sole judge as to whether the nature of the illness came under the cover of professional secrecy.

The International Health Congress.

The International Health Congress to be held in Vienna in September, 1887, promises to be successful. The hereditary Prince of Austria, Crown-Prince Rudolphus, has consented to act as the patron of the Congress; and the Chief of the Cabinet, Count Traffe, has been designated as honorary president. The committee, with Hofrath Schneider at its head, is working energetically to make the Congress successful.

A Lesson in Obstetrics.

A colored physician in one of the Southern States, having a forceps case and being unable to apply the instrument, sent for a white doctor, who in about ten minutes extracted the child. Following him to the door, the colored doctor handed him a five-

dollar bill, saying that he wanted to pay for his lesson in obstetrics.

He Drank Liniment for Cough Syrup.

A despatch from Red Bank, N. J., under date of December 4, says that George W. Burd, a diamond setter of New York, whose residence is at Red Bank, died from the effects of drinking a strong liniment which he mistook for a cough mixture which had been prescribed.

Medicine and the Blue Laws of Boston.

The enforcement of the Puritanical blue laws recently caused a general closing of the apothecary shops in Boston. Many of the apothecaries hung inscriptions which they considered appropriate to the occasion, in their windows, and one is said to have placed in his window a bottle of cholera mixture labeled "Wait till Monday."

Personal.

—Dr. Martin, Dr. H. Wharton, and Dr. Deaver are the prominent candidates for the position of Surgeon at the Philadelphia Hospital, vice Dr. A. S. Roberts, resigned.

—Mr. W. H. Walmsley on last Thursday evening, gave an exhibition of photo-micrographs before the Biological and Microscopical section of the Academy of Natural Sciences, in the hall of the Academy, Nineteenth and Race streets.

—Dr. Thomas G. Morton will deliver the address at the opening of the Orthopædic Hospital in January. He was one of the founders of the hospital.

Items.

—Lady Wilson, widow of the late Sir Erasmus Wilson, died November 6. By her decease the Royal College of Surgeons becomes entitled to the legacy of $1,000,000 left by Sir Erasmus.

—The Pirogoff Surgical Society of St. Petersburg is taking the lead in a movement for providing a central place of meeting for all the medical societies, where also accommodation will be found for all their libraries.

—In a discussion on laparotomy, at the meeting of the American Medical Association, it was stated that in Central Asia little girls were castrated just before menstruation, and in this condition they made very useful house-servants.

—Dr. Henry H. Smith, Chairman of the Executive Committee of the International Medical Congress, announces that the sessions of the Congress will occupy six days. European delegates will consume thirty days in crossing the ocean twice and in attendance upon the Congress.

—In the Saxon town of Colditz, which contains about 5,000 inhabitants, and is situated near Leipzig, a society for leaving nature to cure diseases (naturheilverein) is in course of formation. The six local practitioners have agreed to inform the members that they must not expect medical assistance from them in case they should change their minds.

—A case of poisoning by the roe of herrings is reported in *La France Médicale*, No. 122, by M. Belin. The chief symptoms were vomiting and diarrhœa, attended with severe colic and burning sensations throughout the whole course of the stomach and intestines.

—For some months past an epidemic has been reigning in the Greek seaside town, Nauplia, called by the local physicians ἰκτερος-τύφου. It attacks especially the well-to-do classes, and generally proves fatal in three or four days. The bodies are of a yellow color, and quickly become black. The Athens Sanitary Council describes the disease as pernicious yellow fever, and considers it of a non-infectious character.

—The National Society for Aid to the Sick and Wounded in War (British Red Cross Society), has received decorations of the Red Cross from Prince Alexander, of the Bulgarian Red Cross Society, for presentation to Dr. Fetherstonhaugh and Dr. Lake and Sister Henrietta Stewart, in recognition of their services to the sick and wounded in Bulgaria.

OBITUARY NOTICE.

M. Paul Bert.

A Paris dispatch announces the death, on November 11, of M. Paul Bert, the French scientist and statesman. He was a native of Auxerre, where he was born October 19, 1833. He studied law and medicine in Paris, and in 1868 was appointed Professor of Physiology in the Faculty of Science of Paris. He devoted himself to physiological research, and made many valuable experiments by means of balloons to ascertain the conditions of existence at various altitudes. In August, 1875, he was awarded the biennial prize in the Institute in recognition of his scientific work. M. Bert was elected to

the National Assembly by the Department of Yonne in 1872, and was re-elected in 1876 and 1877, He acted with the extreme Radicals, and advocated various educational schemes, especially an act to exclude the clergy and members of religious orders from the schools of France. When Gambetta came into power in 1881, M. Bert was made Minister of Public Instruction, and in April of the following year he was elected a member of the Academy of Sciences.

John P. Gray, M. D.

Dr. John P. Gray, Superintendent of the State Lunatic Asylum at Utica, N. Y., died November 29.

At the Asylum many expressions of sympathy for the bereaved family were received. Telegrams of condolence were sent by Dr. J. B. Andrews, Superintendent of the Buffalo Asylum; Dr. P. M. Wise, Superintendent of the Willard Asylum; Dr. E. N. Brush, of Philadelphia; Dr. H. Goldthwait, New York; Dr. John B. Hinton, New York; Dr. F. E. Roy, Canada; Dr. Stephen Smith, New York; Dr. J. Strong, Superintendent of the Cleveland Asylum; Major Z. C. Priest, Little Falls; Colonel R. M. Richardson, Syracuse; Dr. Henry M. Hurd, Pontiac, Mich.; Dr. C. F. McDougall, Auburn, and others.

Dr. C. C. Field,

Of Easton, Pa. Dr. Cridland Crocker Field, one of the most widely known physicians and surgeons, died in Easton, December 3, suddenly, of neuralgia of the heart. Though 70 years of age, he was in active practice, and the day before his death was attending patients, apparently in the best of health. He expired in the morning before any of the members of his household, save his two sons, could reachh is bedside. Dr. Field was born on board a vessel just entering New York, on February 18, 1817. Dr. Field leaves three sons: W. Gebron Field, lawyer; G. B. Wood Field and B. Rush Field, physicians; and two daughters, Mrs. Dr. Amidon, of New York, and Miss Belle Field, of Easton.

S. J. Ramsay, M. D.

Dr. S. J. Ramsay died at his residence near Darlington, Md., on Tuesday, October 26, in the 67th year of his age.

Dr. Ramsay was born in Peach Bottom township, York county, Pa., very close to the Pennsylvania and Maryland boundary line. He was graduated in medicine at the Jefferson Medical College, Philadelphia, in the year 1840.

He soon after located for the practice of his profession in the village of Darlington, where he continued uninterruptedly in active practice for a period of thirty years. Subsequently, about fifteen years ago, he removed from Darlington to his farm, near Castleton, where he died. He there divided his attention between farming and medical practice, gradually relinquishing the latter as age increased, and as health grew enfeebled, as it did during the last two or three years of life.

A. F. Erich, M. D.

Dr. A. F. Erich, one of the Faculty of the College of Physicians and Surgeons of Baltimore, died of apoplexy at his residence in Baltimore on December 7. He was widely known as a writer on medical subjects.

Dr. Augustus Frederick Erich was born at Eisleben, Germany, May 4, 1837. His family came to this country in 1856 and settled in Baltimore, where he began the study of medicine, graduating from the Maryland University in 1861. He contributed within the following twenty years many works of value to the profession, and from 1873 to 1876 was editor of the *Baltimore Physician and Surgeon.* In 1873 he was also elected to the Faculty of the College of Baltimore, serving therein during the remainder of his life, his specialty being diseases of women and children.

QUERIES AND REPLIES.

What is Fothergill's Fever Mixture? I see the mixture is spoken of frequently—"Fever Mixture of the Future," I think it is usually written. E. P. R.
Tuscumbia, Ala.

The Food Value of Meat Juice.

Eds. Med. and Surg. Reporter:

Please answer the following question in Medical and Surgical Reporter: What is the food value of meat juice from fresh broiled steak? I use a meat juice press, and get about all the *juice,* but do not know its true food value.
La Fayette, Ala. B. F. Rea, Jr., M. D.

Iodoform for Scrofulous Tumors.

Eds. Med. and Surg. Reporter:

In the Medical and Surgical Reporter of October 23, 1886, page 537, under the head of "Sc ofulous Tumors," a solution of iodoform is recommended. Will you kindly tell me the method of using it?—whether as a local application or by injecting into the tumor, or if otherwise, how?
Van Wert, Ohio. C. B. Reid, M. D.

Reply.—We would suppose that it should be injected into the tumor, though no mention of this was made in the journal from which we derived the information.—Eds. Reporter.

DEATH.

LANGWORTHY.—November 27, 1886, at 5 o'clock a. m., in Clinton, Louisiana, at the residence of Mrs. G. C. Comstock, Dr. Owen P. Langworthy, aged 60 years, 4 months, and 28 days.

Pallas Syringe."

SOLUBLE
PILLS AND GRANULES

UNEQUALLED FOR

Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish.

We desire to call the attention of physicians and others to the following points:

1. The best materials are used in their manufacture.
2. No article required by a formula is ommitted on account of its high cost.
3. No Pills are deficient in weight.
4. The Pills are Coated while soft.
5. There is but one Coating, which is perfectly soluble, and there is no sub-coating of resinous character.
6. The coating is so thin that the Pills are not perceptibly increased in size, and yet it is entirely sufficient to protect the Pills from atmospheric influences, and effectually covers any nauseous taste, thus rendering the Pill easy to be swallowed.
7. The Coating is so transparent as to clearly reveal the color of the mass, and its solubility is not impaired by age.
8. The various masses are so thoroughly worked that the materials are perfectly distribute.
9. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
10. The excipients are peculiarly adapted to the permanent solubility of the mass and its efficient therapeutic action.

Trade in Philadelphia supplied by

ROBERT SHOEMAKER & CO.

Baker's Pure Norwegian Cod Liver Oil.

Established 1830.

Put up in our capsuled bottles with steel engraved label. Will always be found of unequalled quality, and sure to yield the most satisfactory results.

BAKER'S EMULSION.

C. L. Oil with Hypo-phosphites. Made with our unequalled Norwegian Oil, rendering it by common consent the Best Emulsion in the market.

Dahl's Norwegian Malt Extract.

The product of the most celebrated brewery in Norway, infinitely superior in flavor and in tonic properties. The most satisfactory results attend its administration.

Price, $3.60 per dozen.

BAKER'S COD LIVER OIL, WITH EXTRACT OF MALT.

A combination of equal parts of these two potent remedies, in which the taste of oil is completely masked, and rendered quite palatable.

The tonic and nutritive properties of both the Oil and Malt should recommend this article to universal favor.

105-1555S

Platt's Chlorides

THE HOUSEHOLD DISINFECTANT

An odorless, colorless liquid, powerful, efficient and cheap. Diluted with from four to twelve times its bulk of water and sprinkled about it immediately destroys all bad odors, purifies every impure spot and chemically neutralizes all infectious and disease producing matter.

INVALUABLE in the sick room. Sold by Druggists everywhere. Quart bottles 50 cents.

A sample of this popular disinfectant will be sent free to any physician addressing

HENRY B. PLATT,
36 Platt St., New York.

BURN-BRAE

This Hospital, designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at

Clifton Heights, Delaware Co., Pa.,

a few miles west of Philadelphia. The Baltimore Turnpike passes the gate, and Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for nearly a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating facilities perfect, light abundant, constant professional supervision of the Superentendent and his assistant Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe and healthful HOME.

ON THE USE OF CIMICIFUGA IN CHOREA, RHEUMATISM, AND PREGNANCY.

BY D. COLVIN, M. D.,

Of Clyde, N. Y.

I was very much pleased with Dr. Corson's article in your journal of November 6, on the use of the cimicifuga in chorea, and confess that I supposed it to be in more common use with the profession than it seems to be, judging from the doctor's proof to that effect, as I have used it in nearly every case of that malady which has come under my care during the past thirty years, with perfect satisfaction.

Dr. Corson quotes a truthful statement of Dr. Free's, to wit: "The one remedy which is the main reliance of the great majority of practitioners is arsenic." To me, it is surprisingly true that Dr. Free's statement is correct.

It seems to be a hobby with a majority of physicians to give arsenic in chorea, and then contentedly wait "seventy or eighty days" for—what? Not for the arsenic to cure, although they think so, but for it to get well, as a rule, by, what lawyers say, "the statute of limitations." Yet they give arsenic in chorea, as they do in eczema—"hit or miss." I am quite sure, from my long experience with cimicifuga in chorea, that if physicians would be as faithful in its use in this disease as they are with the arsenic, they would be surprised at the early improvement in their cases. Let me also say that during my thirty years' experience with the black snake-root, I have treated but few cases of rheumatism without combining it, or giving it alone, with great relief. Also, I have found it very valuable in mitigating the nervous irritability which is so common in phthisis.

During the past twenty years, I have often given it daily, in pregnancy, during the last month of gestation. It was first brought to my notice, as an agent in chorea, by my father-in-law, about thirty years ago, who was a physician of large country practice, and upon whose farm it grew abundantly. He always gathered it at the proper time, dried it, and made a tincture of the same. He urged me to use it in chorea and rheumatism. I then began its use, and have continued to do so from that time to the present.

I have never been able to abort chorea in the short time spoken of by Dr. Corson, as it is seldom that such young patients can take more than twenty minims of a *good fluid extract* without producing an atrocious headache. However, I increase it when I can.

My principal object in this communication is to advise those who desire (and I hope all will) to test its effects in chorea to be very careful that the preparation with which they use is good, as I know that much which is in the market is very unreliable.

I would advise first, when it is possible, that the physician should gather it, or have it done by some reliable person, *at the proper time.* Should he neglect to do that (and he is shiftless if he does, for it can always be found at the proper time), the next best thing to do (and I say so from fifteen years' experience with his preparations) is to use Squibb's fluid extract of the same, which I

have found to be the nearest reliable of any which I have used.

Something has appeared in the journals lately relative to the use of cimicifuga during the latter part of pregnancy (the author's name I do not now remember), and while I am not quite ready to endorse all he said relative to its effects upon parturition, yet I will cordially recommend it.

I well remember, when a young practitioner, of being told by a farmer's wife that she always took an infusion of it during the last three weeks of her pregnancies, and I almost think 'twould have been unsafe for any one to have criticised her confidence in the effects of the remedy upon her labors, more especially if the criticism had been made in her presence.

Allow me to relate a case (for what it is worth) and I will close this communication.

Mrs. F., aged thirty-six, short, fleshy, and vigorous, desired me to attend her in her fourth confinement. The last child was born eight years before, and she had settled down, happily so, into the belief that it was to be the last.

I was credibly informed by those who were present that her labors had all been severe, and I had no reason to doubt the truth of the information. I discovered that the patient was very despondent, and worried about the future; also, there was more or less chagrin mixed with the most of her troubles. I consoled her the best I could, and encouraged her by saying, that "possibly I should be able to shorten the labor and mitigate her sufferings." I felt that 'twas important to treat her mind, and thus told her what I did.

As time passed on, her dread seemed to increase. About four weeks previous to her labor, I began an increased mental treatment (for that is what critics would call it, yet I cannot believe that was all there was of it), by giving fifteen minims of Squibb's fluid extract of cimicifuga, three times a day after meals. On the morning of the day of her confinement, slight pains came on and continued throughout the forenoon. I was out of town and not expected home before 4 p. m. With no expectation that the labor would be completed until many long hours of suffering had been endured, no great anxiety was manifested at my absence. About 12 o'clock the pains began to be more severe, so much so that the membranes ruptured and the husband was obliged to go into the street and procure the first physician he met. At 3 p. m. the labor was over. I saw her in the evening and found her very happy. All the powers of earth cannot convince that precious mother that "the drops which I (she) took" was not the cause of her easy labor. Who can say they were not?

A short time after this paper was written, and at the close of the above report, a sister-in-law of Mrs. F., who was expecting her fourth confinement, had been taking the cimicifuga about three weeks. She had taken none during the former pregnancies. I had attended her during those labors, and although there was nothing abnormal in them, yet all had been "tedious"—never getting through short of twelve hours, and two of them continuing all night and until the evening of the succeeding day. She had desired "to take such drops as my (her) sister-in-law had taken," and was gratified.

On the night of the 20th inst. she began to have slight pains, yet not severe enough to call for medical aid. At 4 a. m. they began to increase in severity, when I was summoned. The greatest activity of the labor was from five to six o'clock, when it was completed.

Here was an instance of three labors, all of which had been "tedious," while in the fourth the severity of the labor occupied only about two hours. Let any one infer what they please, I cannot resist the conclusion that the cimicifuga had a good influence upon the labor.

CHLOROFORM IN PARTURITION.

BY P. J. FARNSWORTH, M. D.,

Of Clinton, Iowa.

It is a stale witticism of the lying-in room that if a man could have the next one, there would only be two children in the family. Unfortunately the next one falls to the woman, and in order to avoid the pains and perils of child-birth she is willing to still more endanger her life by a resort to drugs and stimulants. It is true abortion is attempted for other reasons, but in many cases this is the principal one. The old punishment of the rack resembles labor, the long, tedious, grinding, tearing pain, that lasts for hours, equals the most cruel punishment ever invented.

In 1847, a very humane physician discovered a safe and certain remedy for abolishing the pains of labor; this was chloroform. He published it to a grateful world, and it was eagerly accepted by most, but a few, principally old practitioners, protested against it. At this late day, we hear some

one repeating their arguments. "It was an innovation on the good old way, contrary to nature and the Scripture. It obviates the curse, it would produce certain bad results, lengthen labor, cause greater hemorrhage, and a train of evils"—none of which have followed. Every new invention or great discovery, of however much benefit to mankind, has had its opponennts and detractors. Witness the cry against vaccination, and the precisely similar objections used by the modern anti-vaccinators. "It is controverting Providence that sends to mortals a grievous disease; it is contrary to nature to introduce into man an animal disease that might or must bring with it a long train of diseases; syphilis has been inoculated, other sores have followed; better bear the ills of small-pox, or die of it."

Is not the greater part of man's work to interfere with nature and bring its laws to serve his purpose? For what else is reason designed? He obstructs the course of the river, and makes it grind his corn, instead of doing it with his teeth, as the savage does. Shall he go back to primitive habits to avoid the danger of a flood, and for the sake of a better set of teeth? What is all this science of medicine, but to interfere with the nature of disease? The man who puts the stone in the end of the bag because his fathers did, or because he did when he was young, still exists, and it is from such mainly that the opposition to chloroform in midwifery comes. In no domain of surgery are anæsthetics more beneficent or more conservative of good.

In a practice of twenty years I have administered chloroform (for that is best adapted to obstetrics) many hundred times, and have never witnessed any bad results; have watched its effects carefully, and compared results with cases where it was objected to. In a large practice, my results have been good—above the average—in regard to tedious labors, post-partum hemorrhages, fever, or convulsions. No two people are exactly alike, and it is the part of the intelligent physician to adapt his remedies to the idiosyncrasies of his patients; this is as true of anæsthetics as of other remedies. It may be inadmissible in some cases, which are easily discerned or manifest themselves at the outset.

Properly managed, chloroform hastens labor. If the woman cries out and struggles, it diverts the attention of the attendants; if she is quiet while having her pains, the time seems long. By noting the time it will be found that there is a conformity of return of pains in any case; this I have noted often. Then in regard to the pains, expulsion is produced by the contraction of the powerful muscles of the uterus. The holding in of the breath, the fixing or straining of the abdominal muscles, is only a diversion of the suffering woman and a waste of strength, that is often productive of direct injury.

I have witnessed two cases of apoplectic seizure during the second stage of labor; the contractions went on, and the child was expelled after insensibility set in, the pains continuing regularly.

I have had a few cases of post-partum hemorrhage, but most of them were in cases where no anæsthetics were used; have never had a case of convulsions since I have used chloroform. Who would do turning or introduce instruments without the aid of an anæsthetic? I have done it, but not willingly. For arm or shoulder presentations, I have, in several cases, brought my patient fully under the influence of the anæsthetic, introduced my hand, pushed up the arm, and by external manipulations with the other hand brought the head so as to engage in the strait, and then had labor progress naturally.

In short, there are many reasons beside that of humanity why labor is more easily and safely managed under the influence of anæsthetics than without them. There are cases where they cannot be used, and cases where they must be discontinued; but they are rare, and can easily be discriminated.

The leading spirit of the times is to mitigate human suffering, to prevent animals from suffering—even science is to be deprived of vivisection, because it gives pain to the brute; yet women, with a safe and harmless remedy at hand, are to suffer intolerable torment because men are calloused to their sufferings, and because their indolence or superstition prevents them from using anæsthetics.

All authorities agree that no fatal result has ever been traced directly to anæsthetics in labor. The manner of using them precludes it, and the other drawbacks are in the imagination of the careless observer.

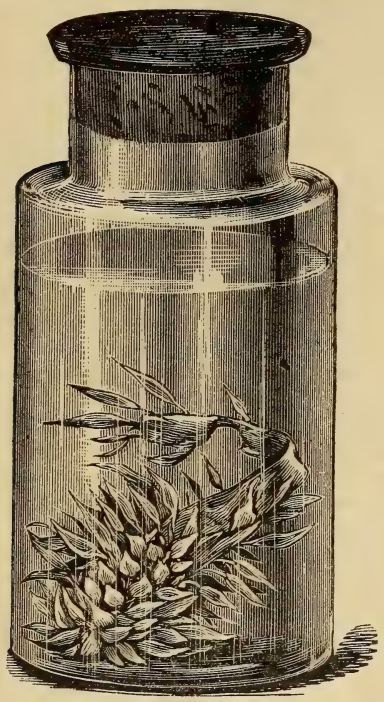
It is unnecessary to give any directions for the use of chloroform in such cases; every text-book contains them; this, with careful attention, is all that is required, and the practitioner who does not avail himself of the benefit of it deserves the rack and torture.

—The College of Physicians of Philadelphia will celebrate the centennial anniversary of its foundation on January 3 and 4.

ENTOZOA—INFORMATION WANTED.

BY E. P. TOWNSEND, M. D.,
Of Camden, N. J.

The accompanying cut is engraved from an exact drawing of a specimen on my table, from a case I report because of its peculiarity and, I presume, rarity, since in my researches I have found nothing similar to it described. I am aware that medical men



are often deceived, or at least the attempt is often made, to deceive by the presentation of false specimens and misrepresentation of symptoms.

The first specimen submitted to my inspection was handed to me by a respectable druggist, with an imperfect history of the case. A few weeks later I asked for another, and submitted them to examination by careful and skillful microscopists. I afterwards had an interview with the lady and elicited the following history of the case:

Mrs. G., of No. — Broadway, Camden, is in her forty-eighth year, is about five feet three inches high, weight 120 pounds, health generally good, and able to do her own house work.

The abdomen is irregular, there being a conical enlargement to the right of the median line, above the line of the umbilicus. About one year ago she had an attack of pain in the bowels, followed by loose alvine dejections. Something attracted her attention, and upon examination she discovered specimens like the one shown in the cut.

Fully supprised and frightened at the character and appearance of this unexpected offspring, she bought and took quantities of "Kunkle's worm medicines." She exhibited to me quantities of pieces, all somewhat similar to this (which is drawn full size), which she kept in a quart preserving-jar to exhibit to her neighbors. Supposing that there might be an element of fraud in the case, I have taken every means in my power to verify her statements. I have carefully tested it to prove, first, whether it was animal or vegetable tissue; second, under the impression that it belonged to the class of hydatid growths.*

I have examined carefully recent specimens for the hooklets peculiar to such growths, but failed to find them or any nuclei. The peculiar shape of the cells is uniform in all specimens. While the quantity passed at one time varies, and the occurrence takes place once or twice a month, except in the matter of decreasing strength, her health is but slightly impaired, and she suffers but little pain and inconvenience.

She is not under any medical treatment, and I have merely examined this case out of curiosity.

I should be pleased if any of your readers can classify it, except under the general term of entozoa.

Should any microscopist desire to examine a specimen, I will supply him with one upon receipt of such a request.

Hospital Reports.

PENNSYLVANIA HOSPITAL.

Service of Dr. Morris Longstreth.

Unusually Rapid Course of Cancer.

The patient who furnished these morbid specimens was a German, only 33 years old, by trade a sausage peddler. At the time of admission to the hospital, only three weeks since, he was a typically well-nourished man. His face was well filled out. He had a double chin, and in fact, though rolls of fat were distinct over the body generally, his flesh was not flabby. His complexion was dark and rugged, and on the whole he looked

*Gross claims, vol. ii., page 624, "That hydatid cysts of liver, may, by a process of elimination, find their way to the bowel.

so well that it was difficult (only three weeks ago) to believe him ill; yet he is now dead, and from cancerous disease.

Six weeks ago the patient for the first time complained of feeling ill, a vague, indefinite sensation of discomfort, but referred chiefly to the stomach. Later, he commenced vomiting, but had no diarrhœa, and without further trouble entered the hospital. His temperature was, however, sub-normal and tongue somewhat coated, though not flabby.

Seven days after admission he complained of pain in the pit of the stomach, but without much tenderness, for he could bear a thorough examination. After this and until his death there was considerable and pretty constant pain in mid-sternum. We endeavored to lessen the vomiting by large doses of subnitrate of bismuth, and used counter-irritation for the pain. Both measures gave apparent relief, for he became more comfortable. Two days ago, on going through the wards, I noticed his pulse was weak, his extremities cold, and his temperature sub-normal.

During that day vomiting increased, and toward evening he died in a condition of *shock*.

The vomited matter was dark-colored, and consisted chiefly of undigested food. The dark color was probably due to admixture of gases with particles of food. This dark color is often produced from an exclusive milk diet and without bismuth.

The stomach.—On removal, before opening, the organ was large—since, it has shrunken. At the lesser curvature we have a thickened mass extending all round the organ, and passing down to the head of the pancreas, which contains throughout scattered lumps of new growth. The pylorus is enormously thickened. We tested its ability to hold water, and it proved good.

Now, this corresponds with what we knew in life. There was *no obstruction*, and the difficulty in examining was due to the great amount of fat over the abdomen. The question of interest is, Why did the patient die in a condition of shock?

Immediately after death, and before the autopsy was made, I thought of duodenal ulcer, which might have ulcerated its way into the abdominal cavity, which, if true, would account for the sudden shock and consequent death. For in such perforation we have shock without much hemorrhage, as in this case. Post-mortem examination revealed extensive metastatic formations of cancerous nodules, chiefly in the liver.

In this case metastasis was very rapid, resulting in the production of emboli. This, then, is the condition that gave rise to shock which proved fatal. At least, the case admits of but two theories. Death was due either to peritonitis suddenly produced, or to rapid embolic metastasis. Why no hemorrhage here? You cannot get hemorrhage ever so slight from cancer, without ulceration. In this case, ulceration had not advanced sufficiently to penetrate the deeper vessels necessary to produce hemorrhage.

The manner of death after so brief an illness was certainly very unusual in a case of carcinoma.

Medical Societies.

LOUISVILLE MEDICAL SOCIETY.

The consideration of the treatment of typhoid fever as announced for discussion was introduced by Dr. Turner Anderson, who said:

"The task assigned to me this evening would be a comparatively easy one if I were given a case of typhoid fever and requested to indicate the treatment appropriate for it; but when I am asked to indicate the treatment which I consider suitable to cases as they occur in practice, I really feel that I have an extensive work ahead of me.

"There is no disease, perhaps, which presents a greater variety of symptomatic phenomena than this; there is no disease perhaps which has so many individual characteristics as typhoid fever. This we all recognize, as was evidenced in the previous discussion concerning this disease, when doubt was expressed by some of the fellows of the Society concerning the character of the cases occurring in the epidemic which recently visited us.

"I have not been unmindful, since my appointment, of the difficulties I must encounter in the presentation of this subject this evening. Professional and other duties have prevented me from systematizing as I should like to have done my ideas in regard to the treatment of this affection, much less to write a paper upon the subject.

"My experience with the disease has been extensive only within the last few years. Neither while in the army nor since, up to 1880, have I encountered many cases. In 1880, and since, I have seen quite a number, and in all forms I suppose in which the disease is presented, viz., the mildest, the mild, and the severe cases of typhoid fever.

"As to the mildest cases, those in which there is scarcely any elevation of temperature, where there is muscular debility, weariness, loss of appetite, extending over a period of three or four weeks, sometimes presenting rose spots, sometimes nothing distinctively characteristic of the disease, which is yet undoubtedly typhoid fever, treatment is actually not called for, and medicine should not be administered.

"The first idea that suggests itself to me when I am called to a case which proves to be typhoid fever is that of prophylaxis, with other members of the family. The question of prophylaxis, with respect to the community, is one which concerns our boards of health; but as regards the extension of the disease in a family, I take it that our first duty is to carefully inquire into any probable source of infection. Any unhygienic conditions should, as far as possible and as soon as possible, be removed. Ordinarily, we discover nothing in particular, and must let the other members take their chances of having the disease.

"I do not myself believe in the personal contagion of typhoid fever. I mention this simply from the fact that I occasionally encounter men of wide experience who believe that typhoid fever is a very slow contagion, but finally operative in a personal way. I was quite surprised recently in consultation in a case of this character to hear a man who has grown old in the practice of medicine express himself as a believer in personal contagion. I myself do not prohibit other members of the family from access to the room in which a relative lies with the disease.

"I have accepted the idea that this is a disease which is communicated through the dejections, and not otherwise; therefore, I am careful in all cases where there is diarrhœa to put in practice the suggestions of Liebermeister in regard to disinfecting the stools, that is to say, I use sulphate of iron and muriatic acid. In this city, in my practice, I find that all dejections from typhoid fever cases go into the vaults and water-closets and into the sewers to be swept away; and where that is the case, I feel it is a duty to disinfect the discharges, and I have made it a point not to neglect it when possible.

"The next question which presents itself as having a practical bearing on treatment is the importance of an early diagnosis. I have not infrequently had persons come to my office having fever, cough, sibilant rales throughout both lungs, and that muscular debility and weariness so characteristic of the first stages of the disease. In the beginning of the last endemic I made the mistake of prescribing for these patients and instructing them to report to me again at my office, when later I would be called to see them at home, and find on my arrival there, on closer investigation, well-marked features of typhoid fever. Experience has taught me not to make mistakes of that kind now. When such cases present themselves now, I order them to go home and to bed at once. That is a matter of the first importance, because in the management of the disease we desire to retain, as much as possible for our patients, their muscular strength.

"The diagnosis then made, let the patient select the best apartment at his command, and place his bed not in a corner of it, but where he can get plenty of pure, fresh air. Then a thermometer should find its place there, and an equable temperature of 65° to 70° be maintained. I have frequently seen most salutary effects follow the recognition of this simple principle when I have been called to patients suffering the discomforts of the first week of the disease, intensified by the air of a heated and close room.

"We must not forget that typhoid fever has definite cycles, or septenary periods, and the management from this time on will depend upon the stage of the disease.

"In the first week we recognize the muscular debility, the anorexia, the tired, weary feeling, the mental dejection, and the cephalalgia—the latter is really the only constant and never absent symptom—this period, I say, we recognize as requiring more attention as regards the comfort of the patient than subsequent periods.

"There are two agents which I have found of value in this period of the disease. The first of these agents is the free use of water. The application of cold water to the head to allay the cephalalgia, and to the body to prevent the temperature from running too high. During this first stage, if the onset has been sudden, if instead of the usual prodromic period the patient takes to bed with a chill immediately followed by a temperature of 103° or 104°, I inquire, as a routine matter, into the condition of the bowels, and usually finding them constipated, I prescribe a laxative or a purgative. I have lately gotten the habit of giving a calomel purge for this purpose. I do not know that it is any better than anything else, but on the principle 'in arrested secretion that it is the recognized cathartic,' I suppose I have preferred it. Then I resort to the administration of opium and bromide of potassium.

"Of these I give enough to relieve the severer symptoms and the cephalalgia, enjoining perfect quiet, and the application, as I have said, of cold cloths to the head, and in this way I generally succeed in keeping the patient quite comfortable during the first week of the disease. I recognize at this time that the disease will run a definite course; that there is no agent known that is in any sense antidotal to the disease. For that reason I resort to no especial line of practice during this or the subsequent periods of the sickness. I mean by this that I have not accepted the idea that the iodide of potassium, iodine, quinine, salicylate of soda, or salicyline, is antidotal to the typhoid fever poison, or especially indicated for the purpose of counteracting it.

"During this period there is always loss of appetite, and I direct the patient to take as little food as possible. It is never difficult to get the patient's consent not to take food, but it is often quite difficult to impress upon attendants the fact that food at this time is not essential. As long as we have fever we have arrested secretion, and the anorexia which occurs at this time is associated with arrested gastric secretion, which renders digestion difficult, if not incapable of taking place properly. I do not exact that no food shall be taken, but I say that water is better than food.

"Now after this period, that is the first week, is passed, I still insist on maintaining absolute quietude in the recumbent position. To accomplish this, I have them begin to use the bed-pan at the start, and direct my patients not to get out of bed for any purpose whatever. I believe this a matter of the utmost importance.

"We recognize the disease to be severe in proportion to the elevation of the temperature, but now we are not all so afraid of high temperature as we were some time ago. I have, I think, myself learned something about the dangers of the high temperature of typhoid fever from the epidemic which originated this discussion. I have learned that a temperature of 104° in the evening, characterizing a severe form of the disease, or of 105°, a quite severe form, is not so alarming, provided it does not remain so for a long period of time. When the temperature runs high, I direct the use of moderately cool water—because I find patients do not well bear the application of cold water—in the form of a sponge-bath. If there is restlessness, and there generally is when the temperature runs up to this point, I recommend the addition of vinegar. Vinegar is agreeable, and has an influence over the sensibility of the nervous centres. As the temperature comes down, then the spongings are discontinued. If there is a morning temperature of 101° and evening temperature of 102° or 102½°, the bath becomes disagreeable, and as the temperature declines they do not require these influences, therefore I never use the sponge-baths unless the temperature runs up to 103½° or 104°, until that time arrives treating them on the expectant plan. If the case then goes on right after the first period is passed, I give no medicine; I simply direct that the body and bed linen be regularly changed, and that absolute recumbency shall be maintained, and let them go on through the disease to terminate favorably spontaneously. That is about my line of practice in favorable cases.

"In cases which do not go on favorably, if I find the temperature going up and the patient progressively worse, as indicated by the frequency of the pulse and by the other symptoms which indicate debility, I then begin with the use of liquid home-made broths, selecting such articles as I think are most easily digested, and alcohol, which I order to be given at stated intervals, in the form of whisky. I never direct a patient to take milk, chicken broth, etc., but I try to do the thinking for the patient, who is now incapacitated from thinking for himself, and I order what I wish him to have at stated intervals. In this we must be governed by the ability of our patients to assimilate what is given. Each individual case presents indications which are important, and which we can only learn by a survey of the case. There are, as regards the use of medicines, about four or five remedial agents that are of any value, and other articles may be reasonably dispensed with. Of these, I would put at the head of the list alcohol; next, opium; next, digitalis; and finally, turpentine. For patients who are restless and vigilant, whose restlessness does not yield to sponging with water and vinegar, I prescribe opium. I never allow my patients to suffer from loss of sleep in typhoid fever. I never allow insomnia to continue for any length of time. I control it by the use of opium. I think its powers of stimulation are such that we have in it an agent whose sustaining influence upon the system counterbalances all the other disagreeable effects which are attributed to it. I am, therefore, in the habit in all cases where there is restlessness and sleeplessness, of resorting to its use. It is especially valuable in those cases characterized by subsultus, and where we have car-

diac exhaustion. It is in these cases, in my estimation, next to alcohol, the very best medicine we can use. In those cases presenting evidences of congestion from cardiac failure, as indicated in cyanosis, sibilant râles, and rapid respirations, I am not afraid of opium, and I give it freely at night. It is especially valuable in those cases that have taken but little nourishment. Where the pulse is very frequent and feeble, where there is delirium and other evidences of exhaustion, apparently indicating early dissolution, I think that opium, with alcohol, has done great good.

"I have seen several cases in the course of the past two years that have, I believe, in this respect, been neglected; cases which have been allowed to suffer from loss of sleep, cases that have taken but a small quantity of alcohol, and that in no systematic way. In these cases, presenting marked evidences of failure, I have seen a large dose of opium quiet the restlessness and put patients to sleep, and after ten or twelve hours awake with perfect convalescence established. I have seen so many of these cases that I have come to the conclusion myself that we have in opium a stimulating and sustaining agent in typhoid fever of great value.

"I saw a man who had been walking about for three weeks with the disease, taking large doses of quinine, in the fourth week presenting all the evidences of circulatory failure as evidenced in the cyanosis, rapid respiration, and râles all over the chest. The case looked hopeless; the man had had no sleep for three days. The urinary secretion was quite well maintained; he had diarrhœa. I gave that man half teaspoonful doses of McMunn's elixir of opium in half an ounce of whisky every two hours till asleep.

"I saw him the next day; the first dose had not quieted him, the second gave him rest; he was now not so tympanitic; the hippocratic countenance marked on the previous day, had given way to the flushed countenance of opium, and he had a good pulse. I continued the use of it, regardless of the condition of the lungs, and in three days he was convalescent.

"Another case, a young man, had been sick five weeks with one of those cases particularly characterized by muscular debility and exhaustion. I was sent for in haste to see him, and when I did so I found him with his fingers drawn tightly into the palms of his hands, delirious, pulse so rapid I could scarcely count it, and he presented all the evidences of cerebral anæmia. I gave him a teaspoonful of McMunn's elixir of opium. He went to sleep, and when I saw him the next day his pulse was well sustained, with that peculiar rhythmical action characteristic of the effect of the drug. That man made a good recovery. In those cases that look as though they are about to terminate fatally, that present evidences of pulmonary congestion, where there is cardiac failure and general exhaustion opium has done more than any one agent I have ever employed.

"As regards the use of digitalis, when the heart-sounds begin to grow feeble, I have considerable faith in its power, but not so much as I have in opium. It undoubtedly gives increased power to the systole, increases the strength of the pulse while it slows it, yet it has not the sustained action which opium gives, and practically I have found the latter preferable.

"As to the quantity of alcohol necessary, that must be decided at the bedside of the patient. I seldom gave more than three ounces to an adult in twenty-four hours, and that I give in milk.

"Turpentine I use, and simply for the purpose of controlling intestinal tympanitis. For the gastric tympanitis we have various carminatives, many of which are effective. For the typhoid fever I do little beyond this. I am not fond of the use of placebos. I tell my patients they need no medicine, and try to control them in that way.

"As regards complications, when they arise I am certainly fond of the administration of certain medicines.

"For intestinal hemorrhage, which is rare, I rely upon two agents: one is the full administration of opium hypodermically as soon as the case is seen, for the purpose of quieting intestinal peristalsis, and maintaining the arterial circulation, immediately followed by a single large dose of turpentine—a dessertspoonful. Whether in typhoid fever, or from any other cause, in intestinal hemorrhage, I have seen greater benefit from this plan than any other I have ever seen adopted. I do not rely upon ergot. I do not believe it is as good as turpentine. Opium to quiet the peristalsis and sustain the action of the heart, and turpentine as a direct hæmostatic and stimulant, constitutes a routine practice with me in intestinal hemorrhage.

"Epistaxis I have had to occur; and when it does, I resort to styptics locally, and the usual mechanical means. I have had no case recently where it was necessary to plug the posterior nares. In one case where I found

it necessary and convenient, I used a guitar string to accomplish it. Fortunately we are not often called upon to resort to extreme measures, and the injection of Monsel's solution into the nose will ordinarily control all hemorrhage.

"I have seen no case of hyperpyrexia, none where the temperature has gone high enough to create a suspicion of it, unless the patient was entering into complications of brain and heart troubles.

"I am careful not to give quinine in typhoid fever. I don't believe it is of much service in this disease; I don't believe it is a medicine of any value except, perhaps, in the latter part of the disease. If it is of value at all it is in convalescence, when the evening rise of temperature seems to occur as a matter of habit. I have tried it thoroughly in the beginning of typhoid fever, and found it would lower the temperature, but just as soon as the effect of the quinine has worn off it goes up again, and nothing, in my estimation, has been gained by the reduction for that short time. I think it especially important we should not give quinine during the first period of the disease. It is a period of discomfort and unrest, of headache and ill-feeling; quinine aggravates all that. I know it is generally given in this period of doubt as to the diagnosis, and just on that account it is misleading. The mineral acids have done little service in my hands. Phosphoric acid I cannot say has done any good; muriatic acid likewise.

"After convalescence has set in, I sometimes give some simple bitters to improve the appetite. Ordinarily as soon as temperature approaches normal, it is more important not to over-feed. There is a considerable amount of vesical irritation in some cases, and this may only make its appearance in convalescence. That can be quickly and uniformly relieved, no matter at what stage it occurs, by the use of the benzoate of ammonia or benzoic acid.

"Before concluding, I wish to return with a few remarks to the subject of bronchitis; I look upon it as it occurs in this disease as being somewhat on the order of asthma—a spasmodic affection of the bronchial tubes, perhaps depending upon the irritation produced in the system by the retention of effete materials, just as we see cases of rheumatic asthma depending upon defective excretion. I believe this the most plausible explanation, and for that reason I think opium does no harm. It quiets the nerve-centres, renders them less susceptible to the disturbance conveyed by the nerves from this seat of irritation, and on that ground is physiologically indicated, and practically I have, as I have said, found it beneficial.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

November 22, 1886. The adjourned annual meeting was called to order by the retiring President, Dr. Daniel Lewis.

Baling Stable Manure.

Dr. John C. Peters read an additional report from the Committee on Hygiene, recommending that the baling of stable manure be enforced in all practical and reasonable ways. The advantage of this method of handling manure was that it could be done within the stables, doing away with filling and emptying sidewalk manure pits. There was great saving in labor and time in handling it, and also in shipping it. A constant demand for it thus packed would be made by fertilizers all over the country, and this would do away with the necessity for manure yards on our river fronts.

Non-Payment of Dues.

A resolution was passed providing for the payment out of the treasury of the dues of honorable members in arrears whose present circumstances would make it embarrassing for them to pay such dues; and the expulsion of those members who could, but would not, pay their dues.

After a brief address by Dr. Lewis, the regular meeting was called to order by the President-elect, Dr. Laurence Johnson, who thanked the Society for the honor conferred upon him, and promised to discharge the duties of the office to the best of his ability. According to usage, he said he would read an address, and although there was nothing new in the subject, he would have to mention his views of the duties of the Society. Among the points which received his attention was the question of the abuse of medical charity, and he divided those who abused such charity into four classes—the wealthy, the well-to-do, the poor, and the paupers. Little could be done to prevent the abuse of medical charities by such of the wealthy as were mean enough to try to avoid paying the physician for his services. The well-to-do sought first to avoid paying the fee of the specialist, who he was of the opinion should charge him no more for his services than did his family physician; but this abuse, for which the family physician might, in part, be responsible, ended with paying no medical fees whatever. The poor, who constituted

nine-tenths of the population of New York, should not be driven to the abuse of medical charities by physicians charging the same price to all patients alike; he should regulate his fee according to the ability of the patient to pay, and this he could do in conformity with the dignity of his profession.

Expulsion of a Member.

The charges brought against Dr. James O'Reilly in an editorial by the *Medical News* had been investigated and found in part to be true, and on recommendation of the Committee on Ethics and the Comitia Minora, he was recommended for discipline, the kind of discipline being expulsion. He was expelled.

The Comitia Minora reported in favor of publishing a medical directory of the city of New York, to be edited by the Comitia. The resolution was adopted.

Memoir of Gaspar Griswold, M. D., M. R. C. S.

Dr. Joseph D. Bryant read the memoir, in which he spoke of the strong mental and physical constitution of the deceased, of his great aptitude for learning, of his industry, of his faithfulness and uprightness as a man and clearness as a writer.

The Society adjourned.

THE BALTIMORE ACADEMY OF MEDICINE.

Stated meeting, October 19, 1886.

Sudden Failure of Heart's Action the Result of Diminution of Atmospheric Pressure.

Dr. Frank Donaldson, jr., referred to a case of sudden failure of heart's action that he had recently seen. The cardiac depression was apparently the result of the diminution in the atmospheric pressure that the patient experienced while in a high altitude.

The same sudden heart failure, he observed, is seen as a result of rarefaction of the air in the pneumatic cabinet. The approach of the heart failure is indicated by a gradually weakening and irregular action of the pulse.

He thinks the cardiac failure due to a diminution of pressure *upon* the heart, while at the same time the pressure *within* the heart remains the same.

Dr. S. C. Chew has never had his attention called to just to such a case, but thinks Dr. Donaldson's explanation a very probable one. He thinks the irregular and tumultuous action of the heart due to a lessened pressure upon the body generally, thus allowing of a universal dilatation of the capillaries.

Dr. F. Donaldson, jr., said that cases of the same nature as the one referred to by him had been seen by other observers—Loomis records 48 of them. Solly has seen a number of these cases in high altitudes, many of whom had never experienced a pre-existing cardiac disturbance previous to their going to these elevations.

Shock Consequent upon Surgical Operations.

Dr. J. J. Chisolm said, at the last meeting attention had been called to the small amount of shock consequent upon surgical operations upon young children. In his experience old persons stand them as well.

A Case of Pleurisy.

Dr. Henry M. Wilson said he had been in attendance upon a lady for about six weeks or two months. She was very carefully nursed by her sister during this time. One day she called his attention to a slight dyspnœa, and referred to a slight pain in the side, only lasting for a few minutes, that she had felt a few nights previous. Upon examination he found the pleura on that side in a state of inflammation, with its cavity filled with fluid and the heart in consequence displaced. Thought it singular that so extensive an inflammation should have been in progress with so few outward symptoms.

Dr. S. C. Chew said often a less extensive inflammation in this locality gave rise to much more pronounced symptoms than where the process is more extensive. He related a case in his own practice similar in general to that of Dr. Wilson. It was in a man, and his pleural cavity became filled with fluid before he was aware of the existence of any trouble whatever of a serious nature.

Peritonitis Due to Perforation of Vermiform Appendix.

Dr. Henry M. Wilson referred to a patient, a man, æt. 27 years, whom he had seen. He found him complaining of a not very severe pain over the abdomen. The next morning he was sent for hurriedly, and found his patient in collapse, from which he aroused him only with the greatest difficulty. The pain continued without being lessened. He diagnosed peritonitis. The man had had during the previous summer moderate pains over the abdomen at different times. Two weeks after having first seen his patient, he died.

Autopsy revealed a swelling containing fluid over the left inguinal ring. It was aspirated, and about three pints of fetid pus

escaped. Within the abdominal cavity there was a massing together, by means of a fibrous exudation of the omentum and intestines in such a way as to form, so to speak, a second diaphragm, dividing the cavity into two distinct parts. The pelvic portion was filled with pus.

The vermiform appendix was perforated, and in the most dependent portion of the pelvic cavity there was found a hard mass of fecal matter about the size of a Minie ball. This mass was without a nucleus, as was shown by section made at a later date. He thinks perforation took place at the time of the extreme collapse to which he referred. He referred to a peculiar pain in the penis that lasted for about half a day, as one of the most prominent symptoms.

Intubation of the Larynx.

Dr. F. Donaldson, Jr., recently intubated the larynx of a child with membranous croup. There was apparently a temporary benefit, but the child died in about eight hours.

Dr. S. C. Chew, who had seen Dr. Donaldson's patient, was yesterday called in consultation to see another child suffering from the same trouble, but in a much more precarious condition. The parents of the child refused to permit any operative procedure. Though he has not seen the patient since, he imagines it must be dead. Does not think tracheotomy or intubation of the larynx would have done any good, as the obstruction was less in the larynx than farther down in the trachea.

Astigmatism in Twins.

Dr. J. J. Chisolm has recently seen two cases of interest—two men, twins, aged nineteen years—each suffering from the same degree of astigatism and of the same angles.

Two girls, twins, aged twelve years each, likewise suffering from the same degree of irregular astigmatism and the same angles.

The Influence of Removal of One Ovary upon the Sex of Subsequent Children.

Dr. S. C. Chew spoke of a young lady from whom one of her ovaries has been removed. As she is about to be married, it will be of interest to note the effect upon the sex of her children.

Dr. B. B. Browne said the theory of removal of an ovary affecting the sex of the subsequent children he thought pretty well abandoned, because of women with but a single ovary having given birth to children of different sexes.

Dr. J. J. Chisolm referred to a case of

Poisoning by Cocaine.

One year ago he operated upon a man for glaucoma. Recently, while on his way up the bay, the man caught cold, and in consequence there was a conjunctivitis set up. He applied to the inflamed conjunctiva a 5 per cent. solution of nitrate of silver, after first having anæsthetized the eye with cocaine. In half an hour sight was reduced in that eye to such an extent that he barely had perception to light. The man had, in consequence of the instillation of cocaine, an acute traumatic glaucoma.

Eserine was applied to the affected organ, with the result of counteracting the action of the cocaine; and in less than three hours its action was apparent, and in five hours sight in that eye was completely restored.

He thinks had eserine not been applied a destructive glaucoma would most certainly have set up. This is the first case of the kind he has seen.

Dr. B. B. Browne has used cocaine with good effect in the vomiting of pregnancy. He administers 10 gtt. of a 2 per cent. solution.

Dr. H. P. C. Wilson exhibited

A Novel Form of Clinical Thermometer

that had recently been purchased in London. It is encased in a locket and can be worn upon the watch chain. It, however, possesses the great disadvantage of not being self-registering.

Stated meeting, November 2, 1886.

Bromide of Ethyl in Conjunction with Chloroform.

Dr. J. J. Chisolm is now employing the bromide of ethyl in conjunction with chloroform as an anæsthetic. His method is to anæsthetize the patient first with bromide of ethyl, and then after discontinuing this agent to keep up the anæsthesia with chloroform. The advantage claimed by him for this method is that he accomplishes the desired result much more quickly than when chloroform is used alone.

Dr. H. P. C. Wilson has been very forcibly impressed with the universal absence of nausea in all patients whom he has seen chloroformed abroad. He has had an opportunity to see a large number of persons anæsthetized in Europe, and has never yet observed nausea in any of them. He has made inquiry, but can get no satisfactory explanation for its absence.

Dr. C. C. Bombaugh asked Dr. Wilson if the frequency of nausea in his cases might not be attributable to impurities in the chloroform. He said ofttimes aldehyde is present in chloroform as an impurity. In

his experience in army surgery he had used it freely, and had had no cases of nausea.

Dr. H. P. C. Wilson replied that he had no reason to suspect the drug used by him, as he never employed any other than Squibb's.

Dr. Samuel Theobald has avoided nausea to a great extent by giving a hypodermic injection of morphia and atropia about thirty minutes before the time for administering the chloroform. The period of recovery after this treatment is quiet and without excitement.

Dr. C. C. Bombaugh asked Dr. Chisolm if he had noticed any decrease in the number of patients nauseated since he has used bromide of ethyl in the early stages of the process of anæsthesia.

Dr. J. J. Chisolm said he had not seen much nausea lately, but could not say that the decrease was due to his plan of operating.

Dr. Christopher Johnston said it was singular how a patient would at one time take an anæsthetic with but little or no discomfort, and at another time the result would be almost fatal. He referred to a child with hare-lip upon whom he had occasion to operate. The fissure was of such a size as to necessitate two operations. The first time he brought the child under the influence of the anæsthetic there was nothing to create alarm, but at the second operation the patient became almost lifeless.

Tracheotomy for Membranous Croup.

Dr. Christopher Johnston spoke of an interesting tracheotomy that he had performed. The history is as follows: On the night of October 6 he was called to see a child, of about three years of age, suffering from membranous croup. The patient was then very ill; stridulous breathing was present. On the morning of October 7 he did tracheotomy, using a Durham tube. For a time the operation gave much relief. For a period of five to seven days there was no attempt to breathe through the larynx, but all the respiration was carried on through the tube in the trachea. After this time there was a considerable swelling on the tissues of the neck, the membranous formation increased, and the formation could be seen in the trachea below the insertion of the tube. The child's strength was supported by the constant administration of brandy. The upper part of the trachea and larynx was completely occluded by false membranes, which were dislodged by passing upwards from the opening in the trachea a director to which was attached a piece of string tied to a bit of linen cloth. Intubation was also resorted to. Paralysis of the throat muscles allowed food to pass into the trachea, and it was extended through the tracheal tube. No air passed through the larynx for nine days. The tube was in the child's neck, in all, a little more than three weeks. After the removal of the tube the child grew better, and is now perfectly well. He calls attenttion to this case as being somewhat an exception to the rule, for it is very rare that a tube can be removed from the trachea at all after it has remained there so long as this one did.

Dr. J. Edwin Michael thinks there are many children whose lives are sacrificed by the neglect of this operation.

Dr. Chris. Johnston thinks one justified in doing this operation for no other purpose than to relieve suffocation. He had also another child suffering from membranous croup or diphtheria in whom he used a spray of nitrate of silver solution. The tissues were supplied with nutriment by obliging the child to breathe an atmosphere of pure oxygen. It recovered from this attack, but eighteen months later he was called on to do tracheotomy on the same child, who had contracted the disease again. The child recovered, but the tube could never be removed. A year afterward the child was suffocated by the accidental occlusion of the tube. Autopsy revealed a cicatricial contraction of the tissues of the larynx. Intubation of the larynx was frequently resorted to, with no good result.

Dr. J. J. Chisolm saw a patient upon whom tracheotomy had been performed one year ago for syphilitic contraction of the larynx. The tube has remained in position for twelve months, and cannot be removed.

Dr. J. Edwin Michael saw a patient who had stenosis of the larynx. Dilatation had constantly been carried on in order that the man might breathe, but upon one occasion this precaution was neglected, and the man began to find breathing becoming more and more difficult until he became quite cyanotic. Dr. H. C. McSherry, who was the physician in attendance, called Dr. Michael in to do tracheotomy. He tried to do laryngotomy, but found the cricoid cartilage ossified. He then made the opening further down. Relief was immediate. This patient wore the tube for months. Dr. McSherry dilated the larynx from the wound upward until the opening in the larynx was sufficiently large to permit closure of the wound in the trachea. There was some interference with his voice, but the man is now living, and in good health.

Dr. Samuel Theobald wished to know if the introduction of these dilators did not give rise to considerable spasm.

Dr. Michael said it did at first, but the muscles soon became tolerant of their presence.

Forward Displacement of the Eyeball, Due to a Tumor.

Dr. J. J. Chisolm related a case that was of interest to himself. It was due to displacement forward of the eyeball, due to the presence of a tumor in the socket. The patient wanted the tumor removed if the eye could be returned to its position.

Upon anæsthetizing the patient, he found the tumor to be an osteoma of the socket tissues, having its origin in the molar bone. The patient was allowed to come from nnder the influence of the chloroform, and told of his condition. He concluded not to be operated upon. This is the second of these cases that he has seen in the past year. In his second case the ball was so far pushed out that he removed it because of the disfigurement it gave rise to.

Dr. Christopher Johnston had had a patient with a tumor of the lachrymal gland. It became so large as to push the eye completely into the inner angle of the socket. On removal of the enlarged gland, the eye receded to its normal position.

Dr. J. J. Chisolm, within a week of the patient just referred to by him, saw a patient with the eye bulged out from an enlarged lachrymal gland. He asked Dr. Theobald if he had ever used hydrogen peroxide for clearing the secretions from offensive ears?

Dr. Theobald had not.

Dr. J. J. Chisolm finds it a very nice method. He first washes out the ear with warm water, then pours in the hydrogen peroxide. It causes an oxidation of the secretions, and in a few minutee the ear is perfectly clean.

NEW YORK ACADEMY OF MEDICINE.

Section in Obstetrics and Diseases of Children.

Stated meeting, November 24, 1886.
Alexander S. Hunter, M. D., Chairman.

The Milk Supply of New York City.

Dr. Cyrus Edson, of the Board of Health, read a brief paper on this subject, in which he said the milk supply of the city was second only to the water supply from a sanitary point of view. The frauds practiced in the sale of milk related to adulteration, contamination, and taking it from diseased animals. Adulteration was practiced usually by the addition of water or the removal of cream, and this constituted the fraud in ninety-nine out of a hundred cases. In order to increase the specific gravity there was sometimes added sugar or salt. The use of chalk or lime was very rare. As milk preservatives there were used carbonate and bicarbonate of sodium, borax, nitrate of sodium, and salicylic acid. The use of these preservatives was regarded by Dr. Edson as very reprehensible. For the detection of any of these frauds a complete chemical analysis was, of course, the best method, but this was not often practical. The lactometer intelligently employed enabled one to judge with a fair degree of accuracy as to whether the milk had been watered or the cream removed. The lactoscope was useful in determining the quantity of fat in the milk, and he had been enabled with it to determine the relative richness of woman's milk.

The causation of disease by milk taken from unhealthy cows was proven by statistics. The city had at present only two milk inspectors, whereas ten should be provided for. The youth should be instructed by the State in matters of hygiene, including the importance of pure milk, and tracts relating to this subject should be distributed through out the country.

The Food of Infants Deprived of Breast Milk.

Dr. J. Lewis Smith thought that the best food for infants deprived of breast milk was cow's milk; that from several cows mixed was better, as constituting a safe average, than that from a single cow. Definite instructions should be given with regard to the dilution of milk. To infants under three weeks three parts of water might be added; between three and six weeks, two parts water; from the sixth week to the third month, one-half water; from the third month to four and a half months, one-third water; after that until the sixth month, or longer, one-fourth water might be added. Condensed milk usually required four parts of water to render it of the richness of ordinary milk. To prevent coagulation in masses, Dr. Smith added instead of water an equal quantity of a gruel made from wheat flour boiled from four to seven days in a bag. Two teaspoonfuls were grated from the central part of the mass, and boiled in a pint of water ten minutes, and the right proportion of this, according to the schedule given,

should be added to the milk. He thought this preparation of flour was better and much cheaper than many of the prepared foods for sale in the shops.

An infant should not be fed oftener than once in two hours and a half, if under three months of age, and once in three hours after this age. Under the sixth week it should receive only an ounce and a half at each meal; at three months it should receive about two and a half ounces; between the third and tenth months it should be increased to three, four, four and a half, and five ounces.

Dr. Joseph E. Winters read a paper on

Artificial Feeding vs. Wet-nursing,

in which he took the ground that for the infant of the rich as well as for that of the poor, artificial feeding was better than wet-nursing, and was attended by a less mortality, as shown by statistics from institutions in Europe and from his own in private practice. He cited a number of instances in which children in a family hand-fed had done better than those of the same family which had had a nurse. Cow's milk was the food employed. A point on which Dr. Winters laid stress was the fact that successful hand-feeding of the infants, was to be assured by the mother, who alone had a special interest in her child; and consequently when a woman abandoned her own child, turning it over to some institution, and went as a wet-nurse, her child died. This was seen where women had raised their children on the breast successfully, until some one told them of a wet-nurse agency, where they could receive twenty-five or thirty dollars a month. Although the result was that her own babe died of neglect, she would repeat the experience for the money received, and the agency would encourage her in doing so, for it received a fee as well. This, too, was an encouragement to the unmarried woman to repeat her error. Thus the rich woman shunned the duty imposed upon her by the natural law, and hired a wet-nurse to the detriment of her own child, at the expense of the life of the child of the wet-nurse, and encouraged immorality among girls. In private practice, Dr. Winters had never had a bottle-fed child die during infancy. Artificial feeding properly directed and carried out by the mother was perfectly successful, yet he did not retract anything which he had said in a former paper regarding the importance of the mother nursing her own child.

Dr. H. C. Haven, of Boston, had had some experience in raising infants on artificial food in an institution with about forty inmates. His experience and observation had taught him that the most important point regarding artificial feeding was to give the infants milk not more than four hours old. The great difficulty in raising infants on milk in cities, was that the milk was so old as to have undergone fermentative changes before reaching the consumer. He had not been successful in raising a single child on any of the artificial foods except milk.

Dr. B. F. Dawson heartily coincided in the remarks made by Dr. Winters, especially in the statement that the babe of the rich woman had a wet-nurse at the expense of the life of the babe of the wet-nurse. He had had no difficulty in raising babes on cow's milk when the mother had followed his instructions implicitly. The difficulty was to prevent them from over-feeding, and feeding too frequently.

After some further discussion the section adjourned.

Editorial Department.

Periscope.

A Fork Removed from the Stomach by Gastrotomy.

At the meeting of the Paris Academy of Medicine, held August 24, Dr. Polaillon presented a fork which he had removed from the stomach of a patient by aid of gastrotomy. He added the following interesting details:

A. C., aged twenty-five years, who was in the habit of giving public performances as a fire-eater, sword-swallower, etc., August 8, entertained some friends of his with various tricks, amongst which the one found most applause by which he caused a fork to disappear in his pharynx and into the œsophagus. In a moment of dyspnœa, which suddenly surprised him, he took a deep inspiration, but at the same time the fork, which he was holding by its pointed ends, slipped from his grasp. After he had inhaled the necessary amount of air he tried repeatedly reaching with his fingers far down the pharynx to catch the fork, but in vain. It glided deeper

and deeper down the œsophagus, and finally entered the stomach.

The only consequence first was several times in succession some bloody expectoration, which had its origin from excretions of the mucous membrane of the pharynx and the œsophagus. The very next day C. continued as usual to give his public exhibitions.

A few days later, however, he experienced a disagreeable sensation in the epigastrium. He now consulted several physicians, one of whom sent him the sixth day after the accident to Polaillon.

The patient appeared a muscular man with but little adipose tissue. He feels the fork in the upper part of the abdomen, and remarks that it is in an oblique position, a little over the umbilicus, in a direction from the left downwards toward the right side. The points of the fork lie deep in the left hypochondrium; the rounded and obtuse end, however, of the handle is situated more outwards and below the umbilicus in the right hypochondrium. The fork is made of tinned iron and of considerable size. Whenever the stomach was empty the patient suffered from pains, and he had tried, therefore, to eat more frequently to ameliorate his condition. Otherwise, all the animal functions were normally executed, and neither hemorrhage nor vomiting has occurred.

On palpating the abdomen, notwithstanding the absence of all adipose tissue, the fork could not be felt, only where, according to the statement of the patient, the handle of the fork was lying, could a hard body be felt, which seemed movable. Pressure at this point caused severe pains in the heart, as if this organ were irritated by the prongs of the fork.

The introduction of the œsophageal sound of Collin with metal-point resonator, which causes in the ear of the investigator a peculiar, well-defined noise as soon as its point touches a foreign body in the stomach—was without any result. P. began to doubt the presence of the fork for this reason, and the more as the introduction of the sound seemed to cause a great annoyance to the patient, although he was in the habit of swallowing whole swords. An electrical œsophageal sound elicited, when introduced into the stomach, a metallic sound, but only for one moment, and the noise never reappeared, though the experiment was repeated. But the following tests by Dr. Trouvé demonstrated the presence of the fork:

1. A magnetic needle of special sensitiveness at once altered its direction when brought near the epigastrium of the patient, and followed his movements.

2. A powerful electro-magnet, placed a few millimetres away from the abdominal wall, on closing the circuit suddenly produced a localized raising of the skin, as if an intra-abdominal body was suddenly attracted with considerable force by the magnet. A small electro-magnet, hung up by a thread, was then held in front of the stomach. It moved to and fro, and as soon as the circuit was closed it dropped against the abdominal wall in the epigastrium and there adhered. This fact proved the existence of an iron foreign body in the upper part of the abdomen.

The fork could not be abstracted per *viam naturalem*, and P., therefore, proceeded to operate under aseptic precautions. From the ninth rib 1 ctm. toward the inner cartilage edge, an incision 7 ctm. long is made in the direction of the ensiform cartilage. The soft parts beneath are singly divided. On cutting through the peritoneum the omentum fell forwards, and it is retained in the abdominal cavity with the aid of a carbolized sponge.

The finger can now easily feel in the stomach the foreign body. A fold of the anterior wall of the stomach is pulled out without difficulty and held over the lips of the wound made by the incision, by two long steel needles, which pass through the base of the fold. A 3 ctm. long incision is made in the wall of the stomach, the fork at once caught with pincers and quickly removed. Three vessels of the wall of the stomach receive a silk ligature. The wound in the stomach is closed with catgut, the steel needles are withdrawn, and the stomach is permitted to slip back. The external wound is well closed with four deep and four superficial sutures, and Lister's bandage finally applied.

The wound healed by first intention, and the patient made an excellent recovery. Thus far the walls of the stomach were always secured to the edges of the external wound, so that a fistula formed, which gradually healed. P., relying upon the modern achievements of surgery, did as above described, and the result justified his method. Very interesting also are the means employed to arrive at a correct diagnosis. Whether the electro-magnet would have given such positive information, had the patient possessed much adipose tissue, cannot be determined, though until proof to the contrary is brought, the question must be denied, as fat is a bad conductor.

A Day in the Great Northern Hospital, London.

Dr. Robert Reyburn thus writes in the *Maryland Med. Jour.:*

Some of the great hospitals of London are very disappointing in their external appearances; many of them were constructed when the ideas of the proper construction of hospitals were very different from those prevalent at the present day; begrimed with the smoke of London, they are so gloomy as almost to justify placing over their portals, Dante's famous inscription over the entrance to the Inferno, "who enters here leaves hope behind."

Nothing of this kind can be said concerning the Great Northern Hospital for the paralyzed and epileptics. This institution is situated in Queen Square, W. C.; it contains all the modern improvements in hospital construction, it is well located, the wards are large and roomy, and it is in every respect a model hospital.

I visited this hospital, July 5, 1886, in company with Surgeon Wm. Adams, M. R. C. S., of London; Surgeon Bishop, of Manchester, and Prof. W. H. Pancoast, of Philadelphia, U. S. Surgeon Adams is one of the prominent surgeons of London, and, it may be remembered, paid a visit to the United States a few years ago. He has devoted special attention to the surgical treatment of deformities resulting from paralysis, and has written a valuable monograph on the cure of anchylosis of the hip-joint, by subcutaneous section of the neck of the femur.

My principal object in visiting the hospital was to see the two patients who had been operated upon by Surgeon Victor Horsley, a few weeks before, for the removal of tumors involving the motor-centres of the brain.

Since my return to the United States, I find recorded in the medical journals two other cases recorded of patients who have likewise been successfully operated upon by Surgeon Horsley, in the same institution. I saw the two patients, who had recovered and were walking about the ward and seemed perfectly well.

The patients were both young men, one about twenty years and the other twenty-two years old. W. P., the first patient, had had removed from the left side of the skull a piece of bone over the motor-centre of the brain, one and three-quarters inches broad by two and one-half inches long.

B., the second patient, was also trephined on the left side of skull and a piece of bone was removed one and one-half inches long by one inch wide; this last patient when brought into the hospital had been suffering from almost continuous epileptiform convulsions, and during the thirteen days previous to the date of the operation, had suffered from twenty-eight hundred of these convulsive attacks.

The house physician, Dr. Wilson, gave an interesting account of the scene that ensued during the operation upon B.—one of these patients. He stated that on opening the calvarium and exposing the dura mater, there was not the slightest perceptible morbid condition discoverable by external examination. The flap of the dura mater was then turned back on the upper portion of the left side of the brain, above and over the motor-centre of the right side of the body; the exposed brain-surface was apparently perfectly healthy, and some doubt existed in the minds of those looking on, as to whether the operation should be proceeded with any farther or not. One can fancy the feelings of the operator when placed in such a position, and the responsibility he must necessarily assume should he continue the operation.

To open a man's skull and expose the brain is a dangerous operation, even when performed under the most pressing necessity and urgent symptoms; but to do it without any apparent lesion existing, requires an amount of boldness and confidence in the diagnosis that few surgeons possess. This case, however, had been seen by Dr. Ferrier, who agreed with Surgeon Horsley that this was a case of cerebral tumor, which required the aid of surgery for its removal. Mr. Victor Horsley therefore proceeded with the operation, and found the tumor imbedded in the brain substance, over and pressing upon the motor-centre of the right side of the body, and situated three-quarters of an inch below and covered by the external surface of the brain.

These cases seemed to me to be one of the most triumphant examples of accurate diagnosis and treatment to be found in the history of modern surgery.

Surgeon Adams also showed me some patients who had been operated upon for the cure of the results of paralysis, specially of the extremities.

Surgeon Adams stated that in many cases of paralysis, after the acute state had passed, the deformity is kept up by the difficulty found in improving the nutrition of the weakened muscles, without at the same time causing the corresponding growth in the healthy muscles of the extremities. His idea is to perform tenotomy of the contracted

muscles so as to restore the parallelism of the affected limbs. By this treatment he has been able to restore many cases to health and usefulness.

Surgeon Adams operated upon a case of deformity of the knee-joint whilst I was present, and showed the skill and dexterity that would be expected from a surgeon of his established reputation.

I received many courtesies from Surgeon Wm. Adams, and also from Surgeon T. Nunn, and promised to return to England in time for the meeting of the British Medical Association at Brighton, held August 10, 1886; but I stayed so long on the continent of Europe, that I was prevented from attending, as I expected.

Operation for Lacerated Perineum.

Dr. R. F. Young thus writes in the *Virginia Medical Monthly:*

June 9th, I was called to see Mrs. D., multipara, aged 48. I found her with a very pallid countenance, and she was very much exhausted from uterine hemorrhage, which, she stated, had been almost constant for two weeks previous. On making a digital examination, I found a complete laceration of the perineum, with the womb retroverted and very much enlarged. I used tampons to check the hemorrhage, but, when removed, the flow would be the same. After two days I lifted the fundus as far forward as possible, and applied a Hodge's closed-lever pessary, with the result that, by relieving the uterus of its own pressure and sagging, the hemorrhage was stopped. The object was to keep the womb in its normal condition, which the pessary failed to do, owing to the absence of perineum.

When I found this state of things, I invited Drs. Wagg and Smith to see the case, and advise as to whether the perineum should be closed. This being decided upon, she was put upon appropriate treatment preparatory to an operation.

It was desirable that the enlarged condition of the womb should be lessened as much as possible; and to this end it was held in position by means of a large cotton ball, saturated with a solution of carbolic acid and Listerine. This ball remained eight days without discomfort, after which it was removed and the vagina was washed out thoroughly. This was repeated several times, with the result of materially lessening the enlarged uterus. I had never left a tampon in the vagina longer than four days, previous to this time, and naturally watched its effect with some anxiety.

On the 18th of August the patient was ready for operation. With the assistance of Drs. Wagg and Smith, and medical students Weiss, Smith, and R. A. Young, I operated for the purpose of restoring the perineum. I had directed her to take castor oil the night before, and on the morning of the operation the bowels were thoroughly evacuated by means of an enema.

It is a pertinent fact that rural practitioners are poorly equipped for surgery; and, owing to this fact more than any other, strong silk whipcord and quill sutures were used. These, however, are as good as to use wire, but not near so fashionable. The quills were made of rubber tubes, with small sticks inserted to make them sufficiently rigid.

When the patient was thoroughly anæsthetized, which was done by means of chloroform, the hips were brought close to the edge of the table. An assistant held firmly each leg with one hand, while with the other the labia and adjacent tissues were stretched firmly and evenly outward, so as to bring thoroughly into view the parts to be denuded. This was done with a small bistoury and artery forceps—the latter being preferred to the tenaculum, for the reason that the mucous membrane could be caught up and held with greater facility.

The parts were denuded by commencing at the edge of the labium on the left, and dissecting a strip across to the right, continuing this up to a previously marked point in the median line of the posterior wall of the vagina.

When this was completed, the next step was to insert the index finger of the left hand into the rectum, and by making firm pressure upward and outward against counter-pressure with a sponge, the hemorrhage was soon checked and the sutures were put in position. Commencing next to the anus, and introducing a needle about an inch from the freshened surface, four deep sutures were introduced, the needle being guided by the index finger of the left hand, and its point of exit facilitated by pressure of the thumb of the left hand on the parts adjacent. When the deep sutures were all in place, they were drawn up and tied securely over the quills. Next came the superficial sutures, which were placed at intervals sufficient to coapt the edges of the denuded surface nicely.

The *after-treatment* consisted in the use of opium sufficient to lock up the bowels for eight days, and evacuating the bladder with scrupulous care, preventing the urine from coming in contact with the wound. When placed in bed the patient's knees were tied firmly together, and kept so for two weeks.

The usual T bandage was omitted, and the only dressing used was carbolic acid and Listerine solution. In this a cloth was saturated and kept constantly applied.

On the seventh day I removed all the sutures, and found that a small slough had occurred by having the first suture drawn too tight, but the upper two-thirds had healed by first intention.

The lower bowel was evacuated *per enemata* of warm water, and the parts washed perfectly three times a day, after which a pledget of cotton, smeared with vaseline, was placed between the buttocks to prevent chafing.

The sloughed surface healed kindly, and granulations from the bottom filled up the cavity without leaving the parts in a distorted condition.

September 8. Mrs. D. is doing well; the parts are perfectly healed. I propose soon to apply some form of pessary to keep her womb in proper position, when, it is hoped, she will be restored to perfect health, and to one member of the family, at least, a joy forever.

Vomiting a Water Tumor.

The correspondent of the *Medical Press*, September 29, writes as follows from France about a girl aged 17:

About two years previously the child fell ill without any apparent cause, felt languid and oppressed, especially when walking fast. She never complained of pain. She was brought to the hospital, and treated as an out-patient, but got no relief. Subsequently the mother noticed her body deformed, the right side bulging out to a considerable extent, and she appeared to have no waist. She brought her again to the hospital, when she was taken in, but she left after a fortnight because she refused to submit to an operation; it was then she was brought to me. Examination revealed a very extraordinary state of affairs indeed. The right side seemed to be filled with liquid from the last floating rib up to the fourth, and the liquid extended across the epigastrium to left side, where it occupied about the inferior third of the pleura. There could not have been less than three quarts, if not more, present, and the deformity of the right side was most apparent, the ribs jutting out considerably. There was no deviation of the vertebral column. The girl could not remember having had pain in that side ever, but dropsy of the pleura was diagnosed. The abdomen presented another phenomenon, for in the left side over the seat of the corresponding ovary, was found a tumor of the size of an infant's head, hard and unyielding, and presenting all the characters of a fibroid. The girl, although over 17, never menstruated, nor was the least sign of puberty present. We decided on tapping the girl, but as she said she was but little inconvenienced by her state, we decided on "letting well enough alone," and ordered a mixture containing iod. pot. and diuretic infusions. She came afterwards every week to the clinic in good spirits, persuading herself she was better, but I saw little improvement. Iod. pot. ointment was ordered to be rubbed on the abdominal tumor, but with little result. However, one day, while she was out in the fields running, she felt herself suddenly sick, and almost immediately she vomited a quantity of pure water in one flow, which she valued at at least two quarts. The vomiting continued all that evening and through the night, and the following day she found to her great surprise and satisfaction that the fibroid (!) tumor had totally disappeared, and that the liquid in the side was three-quarters gone. She lost no time in coming to me, and I found that her position was exactly what has been already stated. The abdomen was quite normal in appearance, and no trace of the tumor was to be found. Mensuration and palpation discovered a great decrease in the liquid of the chest. She was beside herself with joy. The iod. pot. was continued, and improvement was progressive and rapid. She is now nearly 19, and although menstruation has not appeared yet, she is commencing to acquire that rounded form which characterizes puberty. The distended ribs have returned to their normal position, and she works all day, feeling as strong as any other girl of her age. A week ago I examined her, and found no trace of liquid in any place, and passing the finger *per vaginam* I was able to assure myself of the integrity of the uterus. What was the nature of the large tumor in the abdomen, and how did it disappear so suddenly? Of course the diagnosis of a fibroid was wrong; but if it were an ovarian cyst, multilocular ar unilocular, I must confess it was the first time that I had met with such a dense one. It seemed to the touch to have the consistency of a solid growth. Palpation revealed nothing beyond that the tumor was fixed.

Protracted Pregnancy.

Mr. S. W. Woollett thus writes to the *Brit. Med. Jour.*, October 2:

The following case is, I think, of interest medico-legally, and I should be very glad to have the opinion of any gentleman of the medical profession on it:

A girl, aged 16, is stated to have repeatedly had connection with a man, the last occasion being on the night of June 12, 1885. Her menstruation had ceased on June 10, and since that date has not recurred. I was called to visit her on the night of March 19, 1886, having previously been engaged to attend her in confinement. I found the labor-pains strong and regular, and the patient was greatly troubled with vomiting. On examination *per vaginam* I discovered the os dilated to the size of a shilling, and I felt the membranous bag tense and presenting. I saw her again on the next day. The os was then dilated to the size of a florin, but the pains were feeble, and the vomiting had ceased. On March 21 the pains were entirely absent. On March 22 milk had appeared in both breasts. For the next ten days or so I attended the patient daily. She suffered from intense frontal headache, frequent vomiting, hemorrhage from the bowels, and abnormal temperature. On the evening of April 23 she was confined naturally of a well-developed female child, unfortunately not weighed at the time. From June 12, 1885 (the date of the last admitted connection), to March 19, 1886 (the date of the first symptoms of labor), an interval of 280 days took place. From June 12, 1885, to April 23, 1885 (the date of confinement), an interval of 315 days took place. Judging from the absence of menstruation, the attempt at labor on March 19 (the normal date), the appearance of lactation three days later, and the excessive disturbance of the patient's system for the next month, is it possible for a sexual connection taking place on June 12, 1885, to result in the birth of a child on April 23, 1886?

Simpson has recorded cases of protraction in which pregnancy extended 336, 332, 319, and 324 days after the cessation of the last menstrual period. Dr. Meadows has mentioned a case that extended over ten months. Numerous other instances have been recorded by well-known obstetricians. Dr. Playfair has, in his work on Midwifery, described two cases very similar to mine.

I think it is time that steps should be taken, not to fix the duration of pregnancy, but to relieve the mind of the unprofessional public of the absurd notion that protraction beyond a rigid period of time is impossible. Is the human race so distinct from all other species of living beings that separate laws should be created for it? It is a well admitted fact that cows and mares are subject to protracted pregnancies; why not women?

Rare Lesions Produced by Bromide of Potassium.

Dr. R. W. Amidon presented to the New York Pathological Society (October 13), an epileptic woman, who had been under his care four years, taking moderate doses of bromide of potassium—perhaps never more than four or five drachms a day. A little over a year ago she discontinued it, but recently he learned that she had been taking during the past eighteen months a mixture of the bromides amounting to six drachms a day. She then returned to him, and he found the ordinary acne on the face, which, although usually confined to the face and neck, perhaps occasionally reaching to the chest and shoulders, had in his patient, as in two others whom he had seen, invaded the legs, and assumed almost the pustular form. The lesion began in the ordinary way, but became indurated with rather a large base, and ran a chronic course, breaking down and forming what appeared to be a small ulcer. Vesicles, with contents which tended to become cloudy and purulent, formed in rings about the acne spot. After a time the centre of the spot took on a reparative process, and entirely healed, while the pathological changes at the periphery spread, and the vesicles became purulent, dried up, and formed a brownish scab. A section of one of these spots showed that there had not been a true ulcer, but that the skin had simply been denuded of the cuticle, leaving the papillæ intact. He had in no case seen the true skin invaded. The disease did not seem to depend particularly upon the amount of the bromides given. The only treatment which he had seen do good was the thorough application of the actual cautery.

Bichloride of Mercury in Uterine Catarrh.

Dr. E. W. Watson thus writes in the *Therapeutic Gazette:*

Since January last I have been using a solution of bichloride of mercury as an application to the cervical canal and uterine cavity in cases of chronic muco-purulent discharge. Originally it was suggested to my mind by some considerable success with the same agent in gonorrhœa, as recently recommended. The suspected relation between many chronic inflammatory conditions of the female genital organs and gon-

orrhœa still further suggested the use of the bichloride, though in much stronger solution. One-half to one grain to the ounce of water was the strength I employed, and, on trying it, my success was so much better than ever before that I have continued to use it in all possible cases of the kind. It has several manifest advantages. Applied with the cotton-wrapped applicator, it excites no immediate uterine contraction, as iodine, carbolic acid, and other agents generally do. This enables one to make two, three, or more applications in rapid succession, and affords a much better chance for reaching the entire endometrium. It leaves behind it no coagulated mucus, or film of chemically-altered epithelium, as carbolic acid and nitrate of silver do, to be detached and expelled subsequently by a process almost necessarily involving fresh suppuration. A similar solution may, as a final measure, be applied to the whole vaginal membrane as the speculum is withdrawn, and irrigation with hot water or a very weak solution of bichloride continued for some days. In obstinate catarrh of the cervix, with almost endless ropy secretion, I have also had good success, while I do not remember, after many trials, any success worth mentioning with any agent employed previously. In nearly all the cases two or three applications entirely checked discharges of long standing. Sometimes they recurred at the monthlies, but were again checked, for good apparently, by another application. In two cases single applications did the work, and out of the twenty-three cases treated solely in this way, two only resisted treatment, and were entire failures.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The "Chemist's and Druggist's Diary" for 1887, published at 42 Cannon street, London, is as usual replete with advertisements, and well suited to English druggists.

——A careful "Report on Rhinology" and on the treatment of nasal and pharyngo-nasal catarrh, by J. Addison Stucky, of Lexington, Ky., has been published.

——The use of electrolysis in the treatment of inflammatory products of the female pelvis is the subject of a paper by Dr. J. H. Lloyd, of Philadelphia.

——Dr. Robert Battey, of Rome, Ga., familiar to the profession from "Battey's operation," reports in a paper before us seventy consecutive cases of ovariotomy with sixty-eight recoveries and two deaths.

——The President of the Louisiana State Board of Health, Dr. Joseph Holt, has published a history of the outbreak of yellow fever at Biloxi, Miss., and made this occurrence the text of a discussion of inter-state sanitary notification.

——Dr. Chas. L. Gwyn, of Galveston, Texas, in a recent reprint, cites a case of enlarged labia minora with occasional nymphomania, cured by excision.

——Dr. T. D. Crothers, of Hartford, Conn., has added another to his valuable papers on inebriety by a study of certain hereditary and physical phenomena connected with this disease.

BOOK NOTICES.

The Laws of Generation, Sexuality, and Conception. By H. M. Gourrier, M. D., etc. Translated by F. T. Pierce, M. D. 12mo., pp. 94. Price, $1.00. Hygeia Publishing Company, Union Springs, New York, 1886.

The object of the writer of this work is to establish the theory that the sex of the offspring is inversely to the vitality of the parent—that a sexually-weakened father propagates boys, and *vice versa*—and having set up the theory, to draw a series of practical rules from it for the government of marriage. The author is quite too dogmatic in his assertions, but his book contains a number of interesting and valuable reflections.

An Elementary Course in Practical Zoology. By B. P. Colton. Cloth, 8vo., pp. 185. Boston, D. C. Heath & Co., 1886.

For a beginner in zoölogy, this will be found an admirable primer of the science. It is clearly written and full of directions for practical experiments which will interest the learner and insensibly lead him to take a deeper pleasure in the attractions of this fascinating branch of human knowledge.

—The Royal College of Physicians of London has received two thousand pounds under the will of the late Gavin Milroy, one of the earliest workers in sanitary science. Dr. Milroy left the above-mentioned sum for the endowment of a lectureship on public health and sanitation.

THE

Medical and Surgical Reporter.

A WEEKLY JOURNAL,

ISSUED EVERY SATURDAY.

D. G. BRINTON, M. D.,
JOSEPH F. EDWARDS, M. D., } EDITORS.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

115 South Seventh Street, Philadelphia, Pa

THE

QUARTERLY COMPENDIUM

OF

MEDICAL SCIENCE.

The attention of our readers is especially called at this season to the ***QUARTERLY COMPENDIUM,*** which we publish.

It is, in fact, a supplement to the ***REPORTER,*** being made up of articles which have not appeared in the weekly, but yet are of value and interest to the physician.

It contains about 150 pages of reading matter in each number, and the whole four numbers, embracing 600 pages of choice material, will be sent to paid-up subscribers to the ***REPORTER*** for the very moderate price of

ONE DOLLAR,

in advance, for the year.

Address **DR. D. G. BRINTON,**
115 South Seventh Street Philadelphia.

THE PATHS OF FIBRES IN THE BRAIN.

A new method has been invented by Dr. Luys, of Paris, by which, with the aid of special reagents. the various tracts in the brain may be plainly demonstrated. He also made use of gypsum to obtain impressions of the recent preparation, and in this manner succeeded in demonstrating peculiar morphological changes in the brains of hysterical persons. The procedure is as follows:

The brain is first placed into a saturated solution of bichromate of potassium, then put in methyl-alcohol, from whence it is carried into another fluid, which contains chloral to saturation. In this way the brain tissue became so hard that one could lift off parts of the white substance in the same way as we may split wood when following the fibre, or as is observed in the cleavage of minerals.

Upon brains thus prepared two years ago, and on photographic pictures obtained from such preparations, one plainly recognizes the arrangement of two systems of white fibres, which harmoniously group themselves around central gray masses.

The one system, noticeable on the inner surface of the brain, presents itself as a union of radiating thalamo-cortical fibres which radiate from the layers of the thalami towards all points in the cortical periphery. This system of fibres includes the posterior tracts of Koelliker, those of Reil's corona, and finally those of the interior capsule, which latter are to be looked upon as a depending portion of the special fibre systems, which, forming aside from the other a system of its own, considering the course of its fibres from the cortex to the central ganglion, may be called the cortico-striatum fibre system, as the fibres strictly pass from the cortex to the corpus striatum on either side. These special fibres, which form the quasi band of union between the psycho-motoric regions of the cortex and the motor ganglia of the brain, are probably playing an important role in the transmission of intra-cerebral motor impulses.

These same portions, sufficiently hardened, even while still fresh, could be used as models for plaster-of-Paris impressions, the latter thus preserving the anatomical relations in their original state. This method, employed for this purpose, is a recent though valuable one, and has not yet been used by anybody but Luys.

The procedure is of great assistance in class-demonstration, and well merits a more general application.

THE BRAIN OF AN HYSTERICAL PERSON.

The brain of an hysterical female was prepared according to the new method of Dr. Luys, described at another place in this number, and presented to the Academy of Medicine, at Paris, by the doctor. It shows decided changes from the normal in the arrangement of certain convolutions.

The patient died from a disease which had no connection with her hysteria. She suffered from hysterical symptoms, amongst which her nervous irritability and general excitability were specially prominent; convulsive movements rarely occurred, and then only in connection with pain. The patient, during a long life, frequently under medical treatment, could be hypnotized; but these hypnotic states, whenever they were artificially produced, never seemed to have the least influence in quieting her excitability. The patient having died of some intercurrent malady, Dr. Luys made the autopsy and found the following condition in the brain, which had been prepared as above stated:

The morphological irregularities concern mainly the left lobe. At the height of the upper part of the sulcus of Rolando a peculiar arrangement is noted. There exists a supplementary convolution, which, coming from the oval-shaped lobe, is pushed like a wedge between the end of the ascending parietal convolution, which it presses backwards, and the end of the ascending frontal gyrus, which it presses forwards. The two convolutions mentioned also show an enlargement at places, and are never convoluted.

This peculiar arrangement L. has thus far seen only in the brains of the insane, who suffered much with hallucinations.

It seems as if in all persons who seem affected with profound hysteria, which adheres to them all their lifetime, and especially in cases where a strong hereditary element cannot be denied, decided pathological changes in the brain caused the disease.

NOTES AND COMMENTS.

Rupture of the Uterus During Pregnancy.

Before the Medical Society of London, Dr. Lewers said that rupture of the uterus during pregnancy differed in its mode of production from rupture during labor or abortion. He restricted his remarks to those cases in which the rupture occurred at or before the middle period of pregnancy. In Gräfe's monograph on the subject, three hundred cases of rupture of the uterus had been collected, but only thirty-eight of these occurred during pregnancy, and even this number had to be considerably reduced by taking away cases where the diagnosis had not been verified, and others where it had taken place during premature labor. There remained fourteen cases of the so-called "spontaneous rupture," and two due to violence. Two cases had come under his own notice—(1) an unmarried farm-servant, aged thirty-seven, was healthy and strong, and, on the day preceding the accident, had walked four miles. Late at night she was attacked with severe abdominal pain and vomiting, followed by a speedily fatal result. The abdomen was found full of blood, and a fœtus of four months was lying loose in the abdomen. In the second case, a multiparous woman, aged thirty-three, said to be five months pregnant, when bending over a tub, was seized with pain in the abdomen, followed by collapse and vomiting. The abdomen was opened, when a good deal of clotted blood was found, with a fœtus and placenta lying among the intestines. The membranes led down to a rent in the left side of the fundus of the uterus. This was sutured, but the patient died seven hours after the operation. It was evident that the fœtus had never been in the uterus, but had developed in that part of the fallopian tube which passes through the uterine walls. On the whole, Dr. Lewers thought that these so-called spontaneous ruptures were, when not simply rupture of an ordinary extra-fœtal sac, the result of the rupture of an interstitial fœtation.

Dr. Braxton Hicks suggested that accidental hemorrhage, when bound down by the placenta, might cause distension of a portion of the uterine walls, and tear the peritoneal investment. He quoted one or two cases in which he considered this to have taken place.

Erosion in Surgical Practice.

Before the Midland (England) Medical Society Mr. Atkin read a paper on this subject, and drew attention to the increasing frequency of the use of the scoop and curette in the diagnosis and treatment of disease. Scraping appeared to occupy an intermediate position between caustics and the knife. Caustics were often inefficient. They formed chemical compounds with diseased tissues, which not only served to protect subjacent structures, and formed sloughs which retarded healing, but they were with difficulty localized, and were often accompanied by much pain. The knife necessarily re-

moved sound and diseased structures together, and caused greater mutilation. The objection raised by Vincent, of Lyons, that by scraping, neighboring tissues, healthy though softened, might also be removed, had no practical value, The use of the spoons in tuberculous affections, such as pulpy joints, lupus, cold abscesses, and subfascial glands, was alluded to. The early incision and scraping of ischio-rectal abscess, to prevent fistula, was advocated. The scraping and subsequent antiseptic treatment of chronic ulcer of the leg was also discussed, as was also the use, in combination with caustics, of the scoop in cancerous affections of the skin. It was the only available treatment in certain cases. Scraping, in nasopharyngeal tumors, uterine affections, actinomycosis, and empyema, was also mentioned, and its use deprecated in granular ophthalmic and tympanic granulations.

Mr. Garrard spoke of the value of scraping in lupus, and sinuses left in some cases after amputations.

Mr. Snell alluded to the successful use of the scoop in rodent ulcer, and to its use, with care, in some cases of tympanic granulations.

Mr. Pye-Smith thought it well to use caustics in some cases with the curette; free use of the scoop might be made in synovial disease of joints operated upon.

Epileptic Guinea Pigs.

Before the Medical Society of London, Mr. Victor Horsley showed photographs, projected on the screen with lime-light, of guinea pigs suffering from artificially induced epilepsy. The fit was essentially momentary in character, lasting but a few seconds, and so the photographs had to be of the instantaneous order. Hemisection of the spinal cord and exposing the sciatic nerve, nipping it, and closing the wound, were the artificial methods of induction employed. If the skin of the angle of the jaw or that behind the angle of the eye were touched, there was a momentary interval in which the animal seemed dazed or squeaked. This period was followed by a period of tonic spasm, beginning in the head and neck, which were turned towards the side on which the cord was divided. Complete pleurosthotonos followed. Then consciousness was lost, the animal fell on its back, and the limbs were agitated by rapid clonic spasm. If the sympathetic nerve on one side of the neck was divided, no change was noticed in the fits, and if the vessels of the exposed cerebral cortex were watched no change was observed in them; so the fits were probably not due to the sympathetic nervous system. Again, vaso-motor conditions take an appreciable time to develop. So Mr. Horsley considered that the fits were due to a neurosis, which began first on the right side of the brain, explaining the left pleurosthotonos, and then passed over to the left side of the brain.

Nitro-Glycerine.

Dr. L. v. Holst reports in a St. Petersburg journal a number of observations on the action of nitro-glycerine on heart diseases. He considers that it is especially useful where little or no serious organic change in the heart muscle or valves has taken place, and where the affection is mainly due to a debilitated condition of the organ. In angina pectoris Dr. von Holst has found nitro-glycerine very useful; in one case, indeed, it produced a permanent cure. He recommends recourse to this drug instead of to camphor and musk in cases where great cardiac weakness threatens immediate danger to life. He considers that the diuretic action is not due to any direct stimulation of the kidneys, but is a consequence of the regulation of the heart's action. He finds that dropsy, if due to heart weakness, diminishes under the use of nitro-glycerine, but that the renal form is uninfluenced by it. With regard to the dose, the author advises that small quantities should be given at first, and increased gradually, according to the effect on the particular case. The preparation he uses is a 1 per cent. alcoholic solution, and of this he gives from one to six drops three times a day.

Recovery after Operation at an Advanced Age.

Recovery from operation at so great an age is sufficiently rare to warrant the publication of the following case, which Dr. Geo. Owen Willis reports in the *Brit. Med. Jour.*:

"A woman, aged 86, and well in sight of 87, was admitted under my care in 1882, when surgeon to the Monmouth Hospital. She was hearty, and looked very ancient; her lean limbs were covered with the most shrivelled loose skin I had ever seen. Extensive epithelioma of one wrist, ulcerating into the joint, and patches of a like nature upon the anterior surface of the forearm, made her seek relief. The primary exciting cause was an injury whilst picking fruit. Pain, want of rest, and great courage, prompted her to demand operative relief.

"I amputated her forearm just below the

insertion of the biceps muscle. She took ether well, and recovered in less than three weeks, with a certain amount of primary union, whilst there was no sloughing. When discharged the stump was sound. There was no elevation of temperature, yet a rather sudden fall on the fourth day was recovered from after stimulants and hot packs. This summer I found her feeble, but wonderfully well for a woman aged 90."

Case of Iodide of Potassium Eruption.

Dr. S. West showed to the Medical Society of London a drawing of a man in whom the administration of five-grain doses of iodide of potassium had provoked a copious and severe eruption, which ceased on the discontinuance of the remedy, and returned on its resumption.

Dr. Routh asked if the drug was ascertained to be pure, and Dr. Hall asked whether the condition of the kidneys had been ascertained.

Mr. Morgan said he had met with two very similar cases, both caused by small doses.

Mr. Brudenell Carter mentioned that he had learned from Mr. Hutchinson that persons so susceptible to the toxic effects of the drug were equally so to its therapeutical effect.

Dr. West, in reply, said that there was no reason to suppose the iodide to be impure. The man's urine was examined, without the discovery of anything abnormal.

Treatment of Tubercular Meningitis.

The *Revue de Thérapeutique*, after stating that tubercular meningitis kills 25,000 persons every year in France alone, and quoting a passage from Jaccoud, in which he speaks of the powerlessness of medical men to cope with this terrible disease, cites some recent observations of a Swedish physician, M. Warfwinge, on the marvelous effects of a 1 to 5 iodoform ointment rubbed into the previously shaved head in quantities of seventy-five grains, night and morning. During the interval, the head was covered with an oil-skin cap, which was secured by a bandage. M. Warfwinge treated five cases in this way, with a successful result in every case. The first case was treated for seventeen days, the second for nineteen, the third for thirty, the fourth for thirty-two, and the fifth for nine days only. Ordinary remedies were given in addition for any complications which arose, but M. Warfwinge attributes the successful results to the iodoform alone.

Pruritus Ani from the Use of Coffee.

Dr. S. C. Bridgewater, of Dixon Springs, Tenn., reports the following to the *Med. Record:*

Mr. J. H. Y., aged fifty-five years, a rich farmer and stock-raiser, was afflicted with pruritus ani for ten or twelve years, and had tried almost every nostrum that he could hear of, but without success; had applied to quite a number of physicians, and only a few succeeded in giving him some temporary relief. Some time in April or May last he applied to me for treatment, and I advised him to quit the use of coffee. In a few weeks the symptom disappeared, and has not troubled him in the least since; no other treatment was necessary. He has now been using coffee again for breakfast for two months. Another gentleman, P. W. H., a druggist, was describing his symptoms to J. H. Y., who told him of his relief by abstaining from coffee. P. W. H. also quit coffee, and was likewise cured, or got well.

Influence of Cold and Tobacco-smoking on the Rate of Digestion.

Dr. Chudnovski publishes in the *Russkaya Meditsina* an account of a series of observations made on twelve soldiers in a military hospital, who were perfectly healthy with the exception of slight injuries, with the object of determining the effect of cold applications to the epigastrium upon the rapidity of digestion. The stomach-tube was, of course, freely used, and the completion of digestion was taken to be marked by the disappearance of solid particles in the gastric contents, as revealed by drawing them up through the tube. The author found that when ice-bladders were applied next the skin over the region of the stomach, digestion was retarded in nine out of the twelve cases. Six of the men were smokers and six non-smokers. In the former the time required for digestion averaged seven hours, while in the case of non-smokers the mean period of digestion was only six hours.

Tubercular Ulceration of the Vulva and Vagina.

A recent number of the *Viertel. für Dermatologie und Syph.*, contains a paper on a rare case of extensive ulceration of the vulva and vagina, by H. Chiari. A lithographed plate shows the extent and shape of the ulceration in the parts as removed from the patient, aged thirty. Most of the internal organs of the body were the seat of chronic tubercle—lungs, bronchial and mes-

enteric glands, intestines, left supra-renal body, cerebral meninges, liver, spleen, and kidneys. The manner in which the infection of the vulva was effected is discussed, and the suggestion made that the germs from the intestinal disease may have been accidentally inoculated on the site affected. It should be stated that the uterus and its appendages were free from disease, and that the patient was a nullipara.

The Diagnosis of Ascites.

Dr. Tripier, of Lyons, published an article on the means of diagnosing ascites by the vagina (*The Medical Press and Circular*, October 20, 1886). He was led to try this method accidentally. He was attending a young woman for tuberculous pleurisy, and had occasion to examine the uterus. The situation of the os was normal, but when the finger touched it it seemed to fly from it by reason of an abnormal mobility. It could be turned in every sense with the greatest facility. A certain amount of liquid was supposed to be present in the cavity of the pelvis, and thus caused the phenomenon. The patient died, and the autopsy confirmed the suspicion entertained during life. Several times subsequently he had recourse to this method, and found it of great utility. He was able to diagnose the presence of liquid at the very commencement of peritonitis or of cirrhosis, and in heart disease at an early date.

Enlargement of the Lachrymal Glands.

Before an English medical society Mr. Power showed a boy who had come under his care with swelling at the outer side of each orbit. After referring to the great rarity of symmetrical enlargement of the lachrymal glands, Mr. Power said that iodide of potassium, mercury, and iodine all failed when applied locally, and as the swelling, especially on the left side, was getting larger and more painful, the whole left gland was removed by an incision made through the skin. There had been no trouble whatever since the operation (a fortnight previously), and the cornea and conjunctiva were quite moist.

Intra-pulmonary Injections.

Before the Manchester (England) Medical Society, Dr. Arthur Ransome gave the details of one case of gangrene of the lung, and four of phthisis, in which iodoform dissolved in ether, in olive oil, or in oil of eucalyptus, had been employed, the later vehicle being preferred. The case of gangrene of the lungs was restored to health, the treatment having been very thoroughly carried out. In the phthisical cases, only from two to eight injections had been used in each case, and temporary benefit was obtained in two of them. In one of the others, symptoms of iodoform-poisoning had followed an injection, and, in the remaining case, temporary pneumothorax was produced. Hemorrhage from the lung followed one of the injections, in the case of gangrene, but without any bad results.

Tubercular Inoculation in a Man.

Dr. Axel Holst mentions the case (*Lancet*, Oct. 16,) of an attendant on the phthisical patients at a hospital who had suffered for a long time from atonic ulceration of the fingers, which had been treated with ointment, plaster, caustic, and scarification. No tubercle bacilli were to be observed with certainty in the sores. Later the man was affected with a tuberculous glandular swelling of considerable size in the axilla, which contained a considerable number of Koch's bacilli, and Dr. Axel Holst considers that it is highly probable the patient had received infection through the sores.

New Operation for Prolapsus Uteri.

A Mexican medical journal gives an account of an operation practiced by Dr. Malanco for the purpose of forming a kind of false uterine ligament in cases of prolapsus. It consists in passing the trocar from the anterior vaginal fornix to the abdominal wall (taking care, of course, to avoid the bladder), and in applying the actual cautery to the track by means of a thermo-cautery inserted through the canula from the front. The proceeding, which was first proposed by Dr. Fenelon, of Mexico, is stated to have been employed several times with the most successful results.

Hysterical Borborygmus.

To the Midland (England) Medical Society Mr. S. Laurence showed a girl, aged 18, who for the last fifteen months had been subject to constant borborygmi. The sounds were audible at a distance of some yards, and were synchronous with the respiratory movements; they ceased when she was asleep, lying down, or holding her breath. They had obstinately resisted all treatment, and were regarded as hysterical.

A Prescription for Infantile Diarrhœa.

Dr. C. R. Illingworth writes to the *Brit. Med. Jour.* that during the last five or six months he has found the following medicine to answer well for almost every case of infantile diarrhœa in which he has used it:

℞.	Sol. hydrarg. bichlor.,	℥ iss.–℥ ij.
	Potass. iodid.,	gr. viiix.
	Spirit ammon. co.,	℥ ss.
	Sol. acid. carbol. (1 in 20),	℥ j.–℥ ij.
	Tinct. camph. co.,	℥ ss.
	Vel. chloral,	gr. xv.
	Syrupi,	℥ iij.
	Aquam, ad.	℥ iss.

M. ft. mist.—One teaspoonful every three or four hours.

Radical Cure of Hydrocele by Pure Carbolic Acid Injections.

Dr. J. K. Murray writes to the *Brit. Med. Jour.* that J. J., aged 70, had a hydrocele which had been tapped repeatedly during the last five years. On the last occasion iodine had been injected, but the fluid began to reaccumulate in less than a month. In July, 1886, two drachms of pure carbolic acid were injected after tapping. There has been no reaccumulation yet, though four months have elapsed.

Pasteur's Prophylactic in Russia.
